CoFe$_2$O$_4$ nanoparticles prepared by chemical coprecipitation method in a magnetic field exhibit novel magnetic properties. The average particle diameter was about 2 nm and larger depending on the post annealing temperature. Magnetization measurements indicate that smaller nanoparticles are superparamagnetic above their respective blocking temperatures. In the blocked state, these nanoparticles exhibit interesting behaviors in the magnetic hysteresis measurements. Constricted, or wasp waist, with extremely narrow waist, hysteresis curves have been observed in the magnetization versus field sweeps. For larger nanoparticles, the room temperature hysteresis is typical of a ferromagnet with an open loop, but the loop closes at lower temperature. The novel magnetic behavior is attributed to the directional order of Co ions and vacancies in CoFe$_2$O$_4$ established during the coprecipitation of the nanoparticles under an applied field. © 2009 American Institute of Physics. I. INTRODUCTION

Induced magnetic anisotropy due to directional order has been studied since half a century ago.1–4 Directional order of like atom pairs in Co-Ni-Fe alloys, or Co in Co-ferrites, induced by magnetic annealing is responsible for the wasp waist, or constricted, hysteresis curves.5,6 The materials show low or no hysteresis loss in low magnetic fields and exhibit large constant permeability important for applications. Most of the previous studies on CoFe$_2$O$_4$ regarding directional order have focused on bulk or single crystal materials where domain wall motion plays an important role in their magnetic properties.7 Recent advances in nanomaterial preparation have enabled researchers to prepare nanoparticles of Co-ferrites with various newly developed methods, and novel magnetic properties of CoFe$_2$O$_4$ nanoparticles have been revealed. For example, anisotropic nanoparticles were obtained after magnetic annealing,8 and shape control was achieved in the preparation of spinel Co-ferrite nanocrystals.9 Interesting magnetic hysteresis loops associated with cation distribution in spinel structure were observed in epitaxial films grown at low temperature.10 In this paper, we report an interesting hysteresis behavior of single domain CoFe$_2$O$_4$ nanoparticles prepared in an applied magnetic field.

II. EXPERIMENTS AND RESULTS

Cobalt ferrite nanoparticles were prepared by coprecipitation method. The details of the sample preparation is described in Ref. 11, a brief summary is given below. CoCl$_2$·6H$_2$O(AR) and FeCl$_3$·6H$_2$O(AR) were dissolved in purified deoxygenated water, and a small amount of HCl(AR) was added to the solution in order to avoid hydrolyzing. The resulting solution was added dropwise into 1.5 M NaOH(AR) solution under vigorous stirring. The last step generated an instant black precipitate. A magnetic field $H$ =1 T was applied during the procedure. The supernatants were decanted and deoxygenated water added. The precipitates were obtained after washing with ethanol, centrifuging and drying at 60 °C. Some of the as-prepared dried samples were annealed at 300, 600, and 800 °C.

X-ray diffraction data showed that all samples were in the spinel phase of CoFe$_2$O$_4$. The average size $d$ of the particles was estimated using Scherrer formula. $d=2\pi\lambda/(\beta\cos\theta)$, for the as precipitated (dried at 60 °C) sample, and samples subsequently annealed at 300, 600, and 800 °C, respectively. Transmission electron microscopy (TEM) examination confirmed such results. Figure 1 shows the TEM image of the sample annealed at 300 °C, where nanoparticles of 4–5 nm in diameter are seen.

Figure 2 shows the field-cooled and zero-field-cooled magnetizations as a function of temperature of CoFe$_2$O$_4$ nanoparticles dried at 60 °C and subsequently annealed at 300 °C. The samples are superparamagnetic above their respective blocking temperature $T_B=69$ K and 149 K for the 60 and 300 °C samples. The inset shows the typical superparamagnetic $M$ versus $H$ curve of the nanoparticles above their blocking temperatures (measured at 300 K for the latter sample). Using expression $T_B=KV/25k_B$, and anisotropy constant $K=1.96\times10^9\exp(-1.90\times10^{-5}\times T_B)$ J/m$^3$ for CoFe$_2$O$_4$,12 the average particle diameters are found to be about 2.9 and 4.2 nm, which are consistent with the value obtained from x-ray diffraction and TEM. For samples an-
nealed at 600 and 800 °C (particle size of 27 and 40 nm, respectively) ferromagnetic behavior is observed at room temperature.

In the blocked states below the blocking temperature $T_B$, we have observed an interesting magnetic hysteretic behavior that is not commonly seen in CoFe$_2$O$_4$ nanoparticles. An almost ideally constricted hysteresis curve is obtained at low temperature. Figure 3 shows the magnetization versus field curve of a CoFe$_2$O$_4$ sample prepared in a magnetic field and subsequently annealed at 300 °C. The measurement was done at 5 K. In the low field region, the hysteresis loop is closed and linear with a large slope. Both the coercivity and remanence are essentially zero. The hysteretic magnetization is followed by opening of the loop in high fields. We believe this wasp-waisted hysteresis loop with extremely narrow waist should arise from the ordering of the Co ions and vacancies during the precipitation of the nanoparticles. Under the influence of the applied field, the Co ions and vacancies may order preferentially just as they do during magnetic annealing, where the annealing is carried out in an applied field. Studies have demonstrated that the ordering of Co ions on certain lattice sites, Co-vacancy pairs, and Co-Co pairs during magnetic annealing induces a uniaxial anisotropy along given crystallographic orientations. Such directional order is responsible for the constricted hysteresis behavior, which is explained in terms of domain wall motion and pinning by the potential wells formed by the directional

order. The difference here is that the nanoparticles under investigation are single domain. A similar uniaxial anisotropy induced during our sample preparation in magnetic field should be present. We expect an enormously large uniaxial anisotropy overcome, or in concert with, the cubic anisotropy and be the driving force to bring the magnetic moments of the nanoparticles back to their initial directions as the field is brought back to zero. That is to bring the magnetization to the demagnetized state. Detailed study on the mechanism including the interplay between the uniaxial anisotropy and the cubic anisotropy of the CoFe$_2$O$_4$ is, however, needed to fully explain the hysteretic behavior.

For larger particles annealed at 600 °C, the hysteresis at 5 K resembles somewhat that of a sample with ideal uniaxial anisotropy. The relative portion of the magnetization that is hysteretic is reduced as compared to the smaller particles. The magnetization shows tendency to saturate and its value is much closer to the expected 80 emu/g for CoFe$_2$O$_4$, suggesting that the larger nanoparticles are better crystallized.\textsuperscript{7}

Most of the spins are aligned already near zero field, and the coercivity is essentially zero. As the temperature is increased to 300 K, the hysteresis loop opens up with a finite coercivity (see Fig. 4). It becomes that of a typical ferromagnetic CoFe$_2$O$_4$ without induced anisotropy. The uniaxial anisotropy seems to weaken or disappear with increasing temperature rapidly, which suggests a strong temperature dependence of the anisotropy associated with the directional order mechanism and consistent with the previous reports.\textsuperscript{6} Further study is still needed to rule out the possibility that the observed hysteresis at low temperature is due to the coexistence of single domain and superparamagnetic particles in the samples,\textsuperscript{13} such a scenario is however not very likely considering the opening up of the hysteresis loop at room temperature (Fig. 4), when more superparamagnetic particles, if any, are expected than at 5 K.

For the smallest particles (as-precipitated), saturation is far from being reached at 5 T, typical of small magnetic particles, although the directional order induced uniaxial anisotropy exists.

### III. CONCLUSIONS

A uniquely constricted hysteresis loop in CoFe$_2$O$_4$ nanoparticles is observed possibly due to the directional order induced during the sample preparation in an applied magnetic field. In the low field region, the magnetization has zero hysteresis loss and linear field dependence. The hysteresis loop opens up in higher field and thus exhibits a narrow-waisted wasp. This novel behavior of the magnetization in single domain nanoparticles shows similarity, but at the same time distinction, from those observed in multidomain bulk samples. Further study is needed to fully understand the phenomenon, including the various anisotropies at play as well as the order and disorder of the magnetic ions in the CoFe$_2$O$_4$ lattice of the samples.
