ZERO FORCING NUMBER, MAXIMUM NULLITY, AND PATH COVER NUMBER OF SUBDIVIDED GRAPHS

MINERVA CATRAL\(^1\), ANNA CEPEK\(^1\), LESLIE HOGBEN\(^5\), MY HUYNH\(^*\), KIRILL LAZEBNIK\(^\parallel\), TRAVIS PETERS\(^\ast\ast\), AND MICHAEL YOUNG\(^\dagger\dagger\)

Abstract. The zero forcing number, maximum nullity and path cover number of a (simple, undirected) graph are parameters that are important in the study of minimum rank problems. We investigate the effects on these graph parameters when an edge is subdivided to obtain a so-called edge subdivision graph. An open question raised by Barrett et al. is answered in the negative, and we provide additional evidence for an affirmative answer to an other open question in that paper [W. Barrett, R. Bowcutt, M. Cutler, S. Gibelyou, and K. Owens. Minimum rank of edge subdivisions of graphs. Electronic Journal of Linear Algebra, 18:530–563, 2009.]. It is shown that there is an independent relationship between the change in maximum nullity and zero forcing number caused by subdividing an edge once. Bounds on the effect of a single edge subdivision on the path cover number are presented, conditions under which the path cover number is preserved are given, and it is shown that the path cover number and the zero forcing number of a complete subdivision graph need not be equal.

Key words. Zero forcing number, Maximum nullity, Minimum rank, Path cover number, Edge subdivision, Matrix, Multigraph, Graph.

1. Introduction. Let \(F\) be any field. For a (simple, undirected) graph \(G = (V, E)\) that has vertex set \(V = \{1, \ldots, n\}\) and edge set \(E\), \(S(F, G)\) is the set of all symmetric \(n \times n\) matrices \(A\) with entries from \(F\) such that for any non-diagonal entry \(a_{ij}\) in \(A\), \(a_{ij} \neq 0\) if and only if \(ij \in E\). The minimum rank of \(G\) is

\[
\text{mr}(F, G) = \min\{\text{rank} \, A : A \in S(F, G)\},
\]

and the **maximum nullity** of $G$ is

$$M(F, G) = \max \{ \nullity A : A \in S(F, G) \}.$$  

Note that $\mr(F, G) + M(F, G) = |G|$, where $|G|$ is the number of vertices in $G$. Thus the problem of finding the minimum rank of a given graph is equivalent to the problem of determining its maximum nullity.

We say that a graph $H = (V', E')$ is a **subgraph** of $G = (V, E)$ if $V' \subseteq V$ and $E' \subseteq E$. The subgraph $H$ is called an *induced subgraph* if for each $x, y \in V'$, $xy \in E'$ if and only if $xy \in E$. Denote by $G[X]$ the induced subgraph of $G$ with vertex set $X \subseteq V$; $G - W$ is used to denote $G[V \setminus W]$. The graph $G - \{v\}$ is also denoted by $G - v$. A graph $G$ is the union of graphs $G_i = (V_i, E_i)$, $1 \leq i \leq h$, if $G = (\bigcup_{i=1}^{h} V_i, \bigcup_{i=1}^{h} E_i)$. A vertex $v$ of a connected graph $G$ is a cut-vertex if $G - v$ is disconnected. An edge $e$ of a connected graph $G$ is a cut-edge if $G - e$ is disconnected. The **rank spread** of $G$ is $r_e(F, G) = \mr(F, G) - \mr(F, G - v)$. One technique in computing minimum rank is by cut-vertex reduction (see, e.g., [3]), which is as follows: Suppose that $v$ is a cut-vertex of $G$. For $i = 1, \ldots, h$, let $W_i \subseteq V(G)$ be the vertices of the $i$th component of $G - v$ and let $G_i = G[\{v\} \cup W_i]$. Then $\mr(G, F, G) = \sum_{i=1}^{h} \mr(F, G_i - v) + \min \{ 2, \sum_{i=1}^{h} r_e(F, G_i) \}$. For a graph $G = (V, E)$, the degree of $v \in V$, denoted $\deg v$, is the number of vertices in $V$ that share an edge with $v$. A **leaf** vertex is a vertex of degree one. A **high degree** vertex is a vertex of degree greater than or equal to 3.

**Observation 1.1.** Let $G$ be a graph, let $v$ be a leaf vertex of a graph $G$, and let $F$ be a field. It is easy to see that $\mr(F, G) - \mr(F, G - v) \leq 1$, or equivalently, $M(F, G) \geq M(F, G - v)$.

We consider two graph parameters that are related to the maximum nullity, namely the zero forcing number and the path cover number. The **zero forcing number** of a graph is the minimum number of black vertices initially needed to color all vertices black according to the color-change rule. The **color-change rule** is defined as follows: if $G$ is a graph with each vertex colored either white or black, $u$ is a black vertex of $G$ and exactly one neighbor $v$ of $u$ is white, then change the color of $v$ to be black. Let $S$ be a subset of $V$. The derived coloring of $S$ is the result of coloring every vertex in $S$ black and every vertex not in $S$ white, and then applying the color-change rule until no more changes are possible. A **zero forcing set** of $G$ is a set $Z \subseteq V$ such that every vertex in the derived coloring of $Z$ is black. The **zero forcing number** of $G$ is

$$Z(G) = \min \{ |Z| : Z \text{ is a zero forcing set of } G \}.$$ 

A zero forcing set of $G$, $Z$, is called a **minimum zero forcing set** of $G$ if $|Z| = Z(G)$.

A **path** in $G$ is a subgraph $H = (V', E')$ where $V' = \{ u_1, \ldots, u_k \}$ and $E' = \{ u_1 u_2, u_2 u_3, \ldots, u_{k-1} u_k \}$; a path is **even** or **odd** according as its number of vertices is
even or odd. A Hamiltonian path of a graph $G$ is a path that includes all the vertices of $G$. A path cover of $G$ is a set of vertex disjoint paths, each of which is an induced subgraph of $G$, that contains all vertices of $G$. The path cover number of $G$ is

$$P(G) = \min\{|P| : P \text{ is a path cover of } G\}.$$ 

A path cover of $G$, $P$, is called a minimum path cover of $G$ if $|P| = P(G)$.

The relationships between $M(F,G)$, $Z(G)$ and $P(G)$ for any graph $G$ are discussed in papers devoted to the study of minimum rank problems. For extensive surveys on minimum rank and related problems, see [6] or [7].

**Theorem 1.2.** [1] For any graph $G$, $M(F,G) \leq Z(G)$.

**Theorem 1.3.** [8] For any graph $G$, $P(G) \leq Z(G)$.

In [2], examples of graphs are given to show that both $M(F,G) < P(G)$ and $P(G) < M(F,G)$ are possible. In particular, $M(F,G) < Z(G)$ is possible. However, all three parameters give equality for graphs that are trees.

**Theorem 1.4.** [1, 5, 9] For any tree $T$, $M(F,T) = P(T) = Z(T)$.

Following the notation in [3], we give the following definitions. Let $e = uv$ be an edge of $G$. Define $G_e$ to be the graph obtained from $G$ by inserting a new vertex $w$ into $V$, deleting the edge $e$ and inserting edges $uw$ and $wv$. We say that that the edge $e$ has been subdivided and call $G_e$ an edge subdivision of $G$. A complete subdivision graph $G^\ast$ is obtained from a graph $G$ by subdividing every edge of $G$ once. In [3] and [10], the authors investigate the maximum nullity and zero forcing number of graphs obtained by a finite number of edge subdivisions of a given graph and, among other results, establish the following two propositions about the effect of an edge subdivision on the zero forcing number and maximum nullity.

**Proposition 1.5.** [3, 10] Let $G$ be a graph and let $e$ be an edge of $G$. Then

$$M(F,G) \leq M(F,G_e) \leq M(F,G) + 1 \quad \text{and} \quad Z(G) \leq Z(G_e) \leq Z(G) + 1.$$ 

**Proposition 1.6.** [3, 10] Let $G$ be a graph and let $e$ be an edge of $G$ incident to a vertex of degree at most 2. If $F \neq Z_2$, then $M(F,G) = M(F,G_e)$ and $Z(G) = Z(G_e)$.

The paper [3] concludes with a list of open questions, including the following two questions.
Zero Forcing, Maximum Nullity, and Path Covers of Subdivided Graphs

**Question 1.7.** Let $F$ be a field. Suppose $G$ is a graph in which each vertex has degree at least 3 and $H$ is a graph that has one less edge subdivision than $G$. Is it always the case that $M(F, H) < M(F, G)$?

**Question 1.8.** Is $M(F, G) = Z(G)$ for every field $F$ and graph $G$?

In [3], the authors provide the following substantial result toward an affirmative answer to Question 1.8.

**Theorem 1.9.** [3] If $G = (V, E)$ has a Hamiltonian path then $M(F, \overline{G}) = Z(\overline{G}) = m - n + 2$ and $mr(F, \overline{G}) = 2n - 2$, where $n = |V|$ and $m = |E|$.

In Section 2, we provide additional evidence of an affirmative answer to Question 1.8 including establishing that $M(F, \overline{G}) = Z(\overline{G})$ if $G$ does not have a cut-edge. In Section 3, we give an example that provides a negative answer to Question 1.7. We also present examples showing that there is an independent relationship between the change in maximum nullity and zero forcing number caused by a single edge subdivision in a graph $G$. In Section 4, we give bounds on the effect of a single edge subdivision on the path cover number and give conditions under which the path cover number is preserved. We also provide an example to show that $P(\overline{G})$ need not equal $Z(\overline{G})$ for an arbitrary graph $G$.

2. **Complete edge subdivision graphs.** In [3], it was shown that $M(F, \overline{G}) = Z(\overline{G})$ if $G$ has a Hamiltonian path. In this section, we establish $M(F, \overline{G}) = Z(\overline{G})$ for other conditions on $G$, specifically for graphs $G$ such that $G$ is a cactus or has no cut-edge.

A **cactus** is a graph in which any two cycles share at most one vertex. We use Row’s work on cacti to show that the zero forcing number and maximum nullity of a complete subdivision of any cactus is equal.

**Proposition 2.1.** [11] Let $G$ be a cactus in which each cycle has three vertices, an even number of vertices, or a vertex which has only two neighbors. Then $M(\mathbb{R}, G) = Z(G)$.

**Proposition 2.2.** If $G = (V, E)$ is a cactus, then $M(F, \overline{G}) = Z(\overline{G})$.

**Proof.** Let $G = (V, E)$ be a cactus. We perform a complete subdivision on $G$. Notice then that $\overline{G}$ is a cactus. Furthermore, each cycle in $\overline{G}$ is even (and has a vertex of degree two). Thus $M(\mathbb{R}, \overline{G}) = Z(\overline{G})$. If $H$ is a cycle or tree, then $M(F, H) = M(\mathbb{R}, H)$. Since cut-vertex reduction preserves field independence (see [6]), $M(F, \overline{G}) = Z(\overline{G})$ for every cactus $G$. \qed

To prove that $M(F, \overline{G}) = Z(\overline{G})$ for every $G$ that does not have a cut-edge, we first
generalize the set of complete edge subdivision graphs.

**Definition 2.3.** Let \( \mathcal{K} \) be the family of bipartite graphs \( G = (V(G), E(G)) \) such that there is a bipartition of the vertices \( V(G) = X \cup Y \) with \( \deg x \leq 2 \) for all \( x \in X \).

Note that every path is in \( \mathcal{K} \), and every even cycle is in \( \mathcal{K} \). An odd cycle is not bipartite, so it is not in \( \mathcal{K} \). If \( G \) is any connected bipartite graph, then the (unordered) pair of bipartition sets is uniquely determined. If \( G \in \mathcal{K} \) and \( G \) has a high degree vertex, then the bipartition sets \( X \) and \( Y \) such that \( V(G) = X \cup Y \) and \( \deg x \leq 2 \) for all \( x \in X \) are uniquely determined. When the sets \( X \) and \( Y \) such that \( V(G) = X \cup Y \) are not uniquely determined, we often make a choice, possibly subject to some additional condition(s). When \( X \) and \( Y \) are specified by uniqueness or by choice, we write \( X(G) \) for \( X \) and \( Y(G) \) for \( Y \).

**Proposition 2.4.** A graph \( H \) is a complete subdivision graph of some graph \( G \) if and only if \( H \in \mathcal{K} \), \( H \) does not contain a cycle on four vertices, and \( \deg x = 2 \) for every \( x \in X(H) \).

**Proof.** The forward direction is clear. For the converse, we reconstruct \( G \) from \( H \). It is sufficient to do so for a connected graph, and then take the union of connected components, so assume \( H \) is connected. If \( H \) has no high degree vertex, then \( H \) is an even cycle or odd path (an even path is not allowed because one vertex in each bipartition set of such a path has degree one), and thus \( H \) is a complete subdivision graph. So assume \( H \) has a high degree vertex. For each \( x \in X(H) \) with neighbors \( y_1, y_2 \in Y(H) \), delete edges \( xy_1 \) and \( xy_2 \) and vertex \( x \) and add edge \( y_1y_2 \). This method creates a graph \( G \) such that \( H = \overline{G} \). \( G \) is a graph, since no duplicate edges are created (two vertices \( x_1, x_2 \in X \) with the same neighbors \( y_1, y_2 \in Y(G) \) would have created a cycle on four vertices in \( H \), which we expressly disallow).

**Conjecture 2.5.** If \( G \in \mathcal{K} \), then \( M(F, G) = Z(G) \).

By Proposition 2.4, every complete subdivision graph is in \( \mathcal{K} \), so this conjecture generalizes a conjecture that \( M(F, \overline{G}) = Z(\overline{G}) \) for all graphs \( G \).

The method by which we show \( M(F, \overline{G}) = Z(\overline{G}) \) for graphs without a cut-edge requires knowing that certain diagonal entries of a matrix are zero. A graph \( G \in \mathcal{K} \) is **special** if for every \( F \) there exists a matrix \( A \in \mathcal{S}(F, G) \) such that

1. \( \text{null } A = M(F, G) \).
2. If \( x \in X(G) \), then \( a_{xx} = 0 \).

For a special graph \( G \), a matrix \( A \in \mathcal{S}(F, G) \) satisfying conditions (1) and (2) is **optimal** for \( G \).

Let \( G \) be a graph and let \( C = (V_C, E_C) \) be a cycle that is a subgraph of \( G \). A
subdivided chordal path of $G$ is a path $P = (v_1, \ldots, v_{2k+1})$ in $G$ such that $v_1, v_{2k+1} \in V_C$, $\deg_G v_i = 2$ for $i = 2, 3, \ldots, 2k$, and $v_i \notin V_C$ for $i = 2, 3, \ldots, 2k$.

Theorem 2.6. Let $G'$ be a graph in $K$ and let $G$ be obtained from $G'$ by removing a subdivided chordal path $P = (v_1, v_2, v_3)$ of $G'$ between two vertices in $V(G)$. If $M(F, G) = Z(G)$ and $G$ is special, then $M(F, G') = Z(G')$ and $G'$ is special.

Proof. Suppose that $M(F, G) = Z(G)$ and $G$ is special. Let $Q = (v_1, u_2, \ldots, u_{2k}, v_3)$ be another path that connects $v_1$ and $v_3$. Since $G' \in K$ and $v_1, v_3 \in Y(G')$, $\deg_G u_{2i} = \deg_G u_{2i+1} = 2$ for $i = 1, \ldots, k$. Let $A$ be an optimal matrix for $G$, so the diagonal entries of $A$ in the column vectors $a_{u_{2i}}$, associated with vertices $u_{2i}$, $i = 1, \ldots, k$ are all zero. Since the only vertices adjacent to $u_2$ are $v_1$ and $u_3$, $a_{u_2}$ has nonzero entries exactly in rows $v_1$ and $u_3$, and similarly, $a_{u_4}$ has nonzero entries exactly in rows $u_3$ and $u_5$. We can take a linear combination of these two vectors to cancel the nonzero entry in row $u_5$ to obtain a column vector with nonzero entries exactly in rows $v_1, u_3$. We iterate this process with column vectors to obtain a column vector $c$ with nonzero entries in exactly rows $v_1, v_3$. Let $A' = [a_{i,j}']$ be $A$ with the extra column $c$ and extra row $c^T$ and zero as the new diagonal entry. We know $A' \in S(F, G')$. Since $G$ is an induced subgraph of $G'$, $\mr(F, G) \leq \mr(F, G')$. Since $\operatorname{rank}(A') = \operatorname{rank}(A)$, $\mr(F, G) = \mr(F, G')$. Hence, $M(F, G') = M(F, G) + 1$.

Since $a_{x_y}' = 0$ for every $x \in X(G')$, $G'$ is special. Note that $Z(G) + 1 = M(F, G) + 1 = M(F, G') \leq Z(G') \leq Z(G) + 1$. Hence, $Z(G') = M(F, G')$.

Although this paper is primarily concerned with simple graphs, multigraphs are a useful tool. A multigraph $G = (V, E)$ is a general graph in which $E$ is a multiset of two-element subsets of vertices. That is, a multigraph allows multiple copies of an edge $vw$ (where $v \neq w$), but a loop $vv$ is not permitted. For a field $F \neq \mathbb{Z}_2$, the maximum nullity of a multigraph $G$ of order $n$ over $F$, denoted by $M(F, G)$, is the largest possible nullity over all matrices $A \in F^{n \times n}$ whose $ij$th entry $a_{ij}$ (for $i \neq j$) is zero if $i$ and $j$ are not adjacent in $G$, is nonzero if $ij$ is a single edge, and is any element of $F$ if $ij$ is a multiple edge. In the case that $F = \mathbb{Z}_2$ and $ij$ is a multiple edge, $a_{ij}$ is 0 if the number of copies of edge $ij$ is even and 1 if it is odd. If a multigraph does not have any multiple edges then it is a (simple) graph. Observe that if $G$ is a multigraph, then $\overline{G}$ is a (simple) graph and $\overline{G} \in K$.

The contraction of an edge $e = vw$ of $G$ is the multigraph obtained from $G$ by identifying the vertices $u$ and $v$, deleting any loops that arise in this process. A set $R \subset V(G)$ is a separating set of a graph $G$ if $G - R$ has more connected components than $G$ does; in this case $R$ is called an $r$-separating set where $r = |R|$. A 1-separating set is a cut-vertex, and cut-vertex reduction is a standard technique for computing minimum rank/maximum nullity. Van der Holst [12] has established a 2-separating set reduction for computing maximum nullity using multigraphs. A 2-separation of
G is a pair of subgraphs \( (G_1(R), G_2(R)) \) such that \( V(G_1(R)) \cap V(G_2(R)) = R = \{r_1, r_2\} \), \( V(G_1(R)) \cup V(G_2(R)) = V(G) \), \( E(G_1(R)) \cap E(G_2(R)) = \emptyset \), and \( E(G_1(R)) \cup E(G_2(R)) = E(G) \). We introduce some notation for the multigraphs needed for van der Holst’s 2-separation theorem. For \( i = 1,2 \), \( H_i(R) \) is the graph or multigraph obtained from \( G_i(R) \) by adding edge \( r_1r_2 \). If \( r_1r_2 \notin E(G_i(R)) \), \( H_i(R) \) is a (simple) graph; otherwise \( H_i(R) \) is a multigraph having two edges between \( r_1 \) and \( r_2 \) (with every other pair of vertices either nonadjacent or joined by exactly one edge). At most one of \( H_1(R), H_2(R) \) has a multiple edge. For \( i = 1,2 \), \( \hat{G}_i(R) \) is the multigraph obtained from \( H_i(R) \) by contracting an edge \( r_1r_2 \) (note that van der Holst uses the notation \( \overline{G}_i(R) \) for what we denote by \( \hat{G}_i(R) \), but \( \overline{G}_i(R) \) may cause confusion with a complement).

**Theorem 2.7.** [12] Let \( G \) be a (simple) graph, let \( (G_1(R), G_2(R)) \) be a 2-separation of \( G \). Then

\[
M(F,G) = \max \left\{ \begin{array}{c}
M(F,G_1(R)) + M(F,G_2(R)), \\
M(F,H_1(R)) + M(F,H_2(R)), \\
M(F,\hat{G}_1(R)) + M(F,\hat{G}_2(R)), \\
M(F,G_1(R)-r_1) + M(F,G_2(R)-r_1), \\
M(F,G_1(R)-r_2) + M(F,G_2(R)-r_2), \\
M(F,\hat{G}_1(R)-r) + M(F,\hat{G}_2(R)-r) \end{array} \right\} - 2.
\]

**Lemma 2.8.** Let \( G \) be a graph in \( K \) and \( (G_1(R), G_2(R)) \) be a 2-separation of \( G \). If \( G_i(R) \) is an even path with endpoints \( r_1 \) and \( r_2 \) and \( r_1r_2 \notin E(G) \), then \( M(F,G) = M(F,H_1(R)) + M(F,H_2(R)) - 2 \) (or equivalently, \( \text{mr}(F,G) = \text{mr}(F,H_1(R)) + \text{mr}(F,H_2(R)) \) and \( H_1(R), H_2(R) \in K \).

![Fig. 2.1: Illustration for Lemma 2.8](image-url)

Proof. Let \( G_i = G_i(R), H_i = H_i(R), \hat{G}_i = \hat{G}_i(R), i = 1,2 \). Since \( r_1r_2 \notin E(G), H_1 \) and \( H_2 \) are (simple) graphs, and it is clear that \( H_1, H_2 \in K \). To show \( M(F,G) = M(F,H_1) + M(F,H_2) - 2 \), by Theorem 2.7 it suffices to prove the following inequalities.
A decomposition \( L(G) \) of a graph \( G \) is a path and \( H_1 \) is a cycle, \( M(F,G_1) = M(F,H_1) - 1 \). Since \( G_2 \) is obtained from \( H_2 \) by deleting the edge \( r_1r_2 \), \( M(F,H_2) \geq M(F,G_2) - 1 \). Hence,

\[
M(F,H_1) + M(F,H_2) \geq M(F,G_1) + 1 + M(F,G_2) - 1
\]

\[
= M(F,G_1) + M(F,G_2).
\]

- **M(F,H_1) + M(F,H_2) \geq M(F,G_1) + M(F,G_2):** Since \( \hat{G}_1 \) is a cycle, \( M(F,\hat{G}_1) = 2 = M(F,H_1) \). If \( \deg r_2 = 1 \), then \( r_2 \) is a leaf of \( H_2 \), so by Observation \[1\] \( M(F,H_2) \geq M(F,H_2 - r_2) = M(F,\hat{G}_2) \). So assume \( \deg r_2 = 2 \) and let \( r_2y \in E(G) \) and \( r \neq r_2y \). Note that \( r_1y \notin E(G) \) since \( r_1, y \) are in the same bipartition set and \( r_1 \neq y \). Observe that \( H_2 = (\hat{G}_2)_e \) where \( e = r_2y \). By Proposition \[8\] \( M(F,\hat{G}_2) \leq M(F,H_2) \), and the desired inequality follows.

- **For \( i = 1,2 \), **\( M(F,H_1) + M(F,H_2) \geq M(F,G_1 - r_i) + M(F,G_2 - r_i) \): Observe that \( M(F,G_1 - r_i) = 1 = M(F,H_1) - 1 \). Since \( G_2 - r_i = H_2 - r_i \), \( M(F,H_2) \geq M(F,H_2 - r_i) - 1 = M(F,G_2 - r_i) - 1 \), and the desired inequality follows.

- **M(F,H_1) + M(F,H_2) \geq M(F,G_1 - R) + M(F,G_2 - R):** Observe that \( M(F,G_1 - R) = 1 = M(F,H_1) - 1 \). Since \( G_2 - r_1 = H_2 - r_1 \), \( M(F,H_2) \geq M(F,H_2 - r_1) - 1 = M(F,G_2 - r_1) - 1 \). Since \( r_2 \) is a leaf vertex of \( G_2 - r_1 \), \( M(F,G_2 - R) \leq M(F,G_2 - r_1) \), and thus \( M(F,H_2) \geq M(F,G_2 - R) - 1 \). Hence the desired inequality follows.

If \( V(L) \subset V(G) \) and \( A = [a_{uv}] \in S(F,L) \), then the embedding \( \tilde{A} = [\tilde{a}_{uv}] \) of \( A \) for \( G \) is the \( |G| \times |G| \) matrix defined by \( \tilde{a}_{uv} = a_{uv} \) if \( u,v \in V(L) \) and 0 otherwise. A **decomposition** of a graph \( G \) is a pair of graphs \((L_1, L_2)\) such that

1. \( V(G) = V(L_1) \cup V(L_2) \).
2. \( |V(L_1) \cap V(L_2)| = 2 \).
3. \( |E(L_1) \cap E(L_2)| = 0 \) or 1.
4. \( E(G) = (E(L_1) \cup E(L_2)) \setminus (E(L_1) \cap E(L_2)) \).

Every 2-separation \((G_1(R),G_2(R))\) of \( G \) is a decomposition of \( G \), but not conversely. A decomposition \((L_1, L_2)\) of a graph \( G \in \mathcal{K} \) is a special decomposition if it satisfies all of the following conditions:

1. \( L_1, L_2 \in \mathcal{K} \).
2. For all \( F \), \( \text{mr}(F,G) = \text{mr}(F,L_1) + \text{mr}(F,L_2) \). Equivalently, \( M(F,G) = M(F,L_1) + M(F,L_2) - 2 \).
3. For \( r \in V(L_1) \cap V(L_2) \), either \( r \in Y(L_1) \cap Y(L_2) \) or \( r \in X(L_1) \cap X(L_2) \).

**Lemma 2.9.** Suppose \((L_1, L_2)\) is a decomposition of a graph \( G \). If \( A_k \in S(F,L_k) \), \( k = 1,2 \), then there exists \( \alpha \in F \) such that \( A = A_1 + \alpha A_2 \in S(F,G) \). If \( \text{mr}(F,G) = \text{mr}(F,L_1) + \text{mr}(F,L_2) \) and \( \text{rank} A_k = \text{mr}(F,L_k) \), for \( k = 1,2 \), then \( \text{rank} A = \text{mr}(F,G) \) (for this \( \alpha \)). If \((L_1, L_2)\) is a special decomposition of \( G \in \mathcal{K} \) and \( L_1 \) and \( L_2 \) are special,
then $G$ is special.

Proof. If $E(L_1) \cap E(L_2) = \emptyset$, choose $\alpha = 1$. If $E(L_1) \cap E(L_2) = \{zw\}$ choose $\alpha = -a_{zw}/a_{zw}$ where $A_k = [a_{ij}^{(k)}], k = 1, 2$. Then $A \in S(F,G)$ and rank $A \leq$ rank $A_1 + r$ rank $A_2$, so $\text{mr}(F,G) = \text{mr}(F,L_1) + \text{mr}(F,L_2)$ implies rank $A = \text{mr}(F,G)$.

Now suppose $(L_1, L_2)$ is a special decomposition of $G$ and $L_1, L_2$ are special. Construct $A = [a_{ij}]$ as previously using optimal $A_k$ for $L_k, k = 1, 2$. We claim $A$ is optimal for $G$ and thus $G$ is special. It is already established that null $A = \text{M}(F,G)$ and since for $r \in V(L_1) \cap V(L_2)$, either $r \in Y(L_1) \cap Y(L_2)$ or $r \in X(L_1) \cap X(L_2)$, the required zeros on the diagonal are preserved. $\blacksquare$

**Theorem 2.10.** Let $G'$ be a graph in $K$ and let $G$ be obtained from $G'$ by removing a subdivided chordal path $P = (v_1, \ldots, v_{2k+1})$ of $G'$ between two vertices in $V(G)$. If $\text{M}(F,G) = Z(G)$ and $G$ is special, then $\text{M}(F,G') = Z(G')$ and $G'$ is special.

Proof. Theorem 2.8 covers the case $k = 1$, so assume $k \geq 2$. Let $r_1 = v_1, r_2 = v_{2k}$, and $R = \{r_1, r_2\}$. Let $G_1(R) = (r_1, v_2, \ldots, v_{2k-1}, r_2)$ be a path in $G'$ and $G_2(R) = G' - \{v_2, \ldots, v_{2k-1}\}$, so $(G_1(R), G_2(R))$ is a 2-separation of $G'$ (see Figure 2.2). Since $r_1r_2 \notin E(G')$, $H_1$ is a cycle on $2k$ vertices and $H_2$ is obtained from $G$ by adding the subdivided chordal path $(v_1, r_2, v_{2k+1})$ (see Figure 2.2). By Theorem 2.8, $H_2$ is special and by Lemma 2.8, $\text{mr}(F,G') = \text{mr}(F,H_1) + \text{mr}(F,H_2)$. Thus $(H_1, H_2)$ is a special decomposition of $G'$, and so by Lemma 2.10, $G'$ is special. Furthermore, we have

$$\text{M}(F,G') = \text{M}(F,H_1) + \text{M}(F,H_2) - 2$$

by subdividing edges incident to a vertex of degree two. $\blacksquare$

![Fig. 2.2: Illustration for Theorem 2.10](image)

**Lemma 2.11.** Let $G$ be a graph. If cycles $C_1$, $C_2$ of $G$ intersect in $k > 1$ paths,
then there is a cycle $C_3$ of $G$ such that $C_1$ and $C_3$ intersect in exactly one path and that path has at least two vertices.

![Fig. 2.3: Illustration for Lemma 2.11.](image)

**Proof.** Choose an orientation for $C_1$. With this orientation, each vertex $v \in C_1$ has a predecessor and a successor. Let $P = (u_1, \ldots, u_p)$ be a path in $C_1 \cap C_2$ that conforms to the orientation and that is maximal in the sense that the predecessor of $u_1$ in $C_1$ is not in $C_2$ and the successor of $u_p$ in $C_1$ is not in $C_2$. Impose the orientation of $P$ on $C_2$. Let $w$ be the first vertex in $C_2$ after $u_p$ that is also in $C_1$ (see Figure 2.3). Define $C_3$ to be the cycle enclosed by $P_1$ and $P_2$. Then $C_1$ intersects $C_3$ in exactly $P_1$, and $u_p, w \in V(P_1)$.

**Lemma 2.12.** Let $G$ be a graph in $K$. Suppose cycles $C_1, C_2$ of $G$ intersect in exactly one path $P$ and none of the interior vertices of $P$ is a cut-vertex. Then $G$ contains a subdivided chordal path of some cycle.

**Proof.** Let $P = (v_1, \ldots, v_m)$. The proof is by strong induction on the number $\ell$ of high degree vertices among the interior vertices $v_i, i = 2, \ldots, m - 1$. If $\ell = 0$, then $P$ is a subdivided chordal path of $G$. So assume that if two cycles of $G$ intersect in exactly one path that has $q < \ell$ high degree interior vertices, then $G$ contains a subdivided chordal path, and suppose $P$ has $\ell$ high degree interior vertices. Let $v_t$ be a high degree interior vertex. Since $v_t$ is not a cut-vertex, there exists a path $Q_1$ that connects $v_t$ to some other vertex $y \in V(C_1)$ (if necessary reverse the names of $C_1$ and $C_2$) and such that $V(Q) \cap V(C_1) = \{v_t, y\}$. We consider two cases depending on whether or not $y$ is on $P$, as illustrated in Figure 2.4.

**Case 1.** $y \notin V(P)$: Let $Q_2$ be the path in $C_1$ between $y$ and $v_t$ that does not contain $v_m$. Then $(v_1, v_2, \ldots, v_t), Q_1$, and $Q_2$ form a cycle $C_3$ that intersects $C_2$ in path $P' = (v_1, v_2, \ldots, v_t)$. Since $P'$ has fewer high degree interior vertices, $G$ contains a subdivided chordal path.
**Case 2.** $y \in V(P)$: Let $P'$ be the subpath of $P$ between $v_s = y$ and $v_t$, so $P'$ and $Q_1$ form a cycle $C_3$ that intersects $C_2$ in path $P' = (v_s, \ldots, v_t)$. Since $P'$ has fewer high degree interior vertices, $G$ contains a subdivided chordal path.

**Proposition 2.13.** Suppose $G$ has a cut-vertex $v$. For $i = 1, \ldots, h$, let $W_i \subseteq V(G)$ be the vertices of the $i$th component of $G - v$ and let $G_i$ be the subgraph induced by $\{v\} \cup W_i$. If $r_v(F, G_i) = 0$, then

$$mr(F, G) = mr(F, G_1) + mr(F, G - W_1).$$

**Proof.** By cut-vertex reduction

$$mr(F, G) = \sum_{i=1}^{h} mr(F, G_i - v) + \min\{2, \sum_{i=1}^{k} r_v(F, G_i)\}.$$

Since $r_v(F, G_1) = 0$, we have

$$mr(F, G) = mr(F, G_1 - v) + \sum_{i=2}^{k} mr(F, G_i - v) + \min\{2, \sum_{i=2}^{k} r_v(F, G_i)\} = mr(F, G_1) + mr(F, G - W_1).$$

**Proposition 2.14.** Let $G = (V, E)$ be a graph containing a cycle $C$ on $k \geq 3$ vertices that contains exactly one high degree vertex, $v$. Then $mr(F, G) = mr(F, C) + mr(F, G - V(C - v))$, or equivalently, $M(F, G) = M(F, G - V(C - v)) + 1$. Furthermore, $Z(G) \leq Z(G - V(C - v)) + 1$. If $M(F, G - V(C - v)) = Z(G - V(C - v))$, then $M(F, G) = Z(G)$.

**Proof.** From Proposition 2.13, $mr(F, G) = mr(F, C) + mr(F, G - V(C - v))$, so

$$|G| - M(F, G) = (k - 2) + |G| - (k - 1) - M(F, G - V(C - v)).$$
or $M(F, G) = M(F, G - V(C - v)) + 1$. To establish $Z(G) \leq Z(G - V(C - v)) + 1$, we exhibit a zero forcing set of order $Z(G - V(C - v)) + 1$. Let $B$ be a minimum zero forcing set for $G - V(C - v)$, and let $x$ be a neighbor of $v$ in $C$. Then $B \cup \{x\}$ is a zero forcing set for $G$. If $M(F, G - V(C - v)) = Z(G - V(C - v))$, then $Z(G - V(C - v)) + 1 = M(F, G - V(C - v)) + 1 = M(F, G) \leq Z(G) \leq Z(G - V(C - v)) + 1$ so we have equality throughout.

**Remark 2.15.** Every cycle on an even number of vertices is special. Specifically, for a cycle $C$ on $2k$ vertices, the adjacency matrix is optimal if $k$ is even, and if $k$ is odd, an optimal matrix is $A = [a_{ij}] \in S(F, C)$ where $a_{i,i+1} = 1$, $i = 1, \ldots, 2k - 1$ and $a_{1,2k} = -1$ (this is valid over every field $F$).

**Theorem 2.16.** If $G$ is a graph in $\mathcal{K}$ that does not have a cut-edge, then $G$ is special and $M(F, G) = Z(G)$.

**Proof.** We prove the following two statements by induction on the number of cycles for a connected graph $G \in \mathcal{K}$ that does not have a cut-edge.

(A) $G$ is a cycle or $G$ contains a cycle with exactly one high degree vertex or $G$ has a subdivided chordal path.

(B) $G$ is special and $M(F, G) = Z(G)$.

Both (A) and (B) are clear for all cycles in $\mathcal{K}$, and thus for all connected graphs $G \in \mathcal{K}$ such that $G$ has no cut edge and at most one cycle. Assume both (A) and (B) are true for all connected graphs $G$ having no cut-edge and at most $k \geq 1$ cycles. Let $G'$ be a connected graph in $\mathcal{K}$ that does not have a cut-edge and has $k + 1$ cycles.

**Case 1.** $G'$ has a cut-vertex: If $G'$ has a cycle with exactly one high degree vertex, then (A) is true and (B) follows from Proposition 2.14 and the induction hypothesis. If $G'$ does not have a cycle with exactly one high degree vertex, then consider the blocks $G_1, \ldots, G_b$ of $G'$. Since $G'$ has a cut-vertex and no cut-edge, $b > 1$ and each block contains a cycle. Thus $G_1$ has fewer than $k + 1$ cycles. Since $G'$ does not contain a cycle with exactly one high degree vertex, $G_1$ is not a cycle and does not contain a cycle with at most one high degree vertex. By the induction hypothesis, $G_1$ contains a subdivided chordal path. Since $G_1$ is a block of $G'$, $G'$ contains a subdivided chordal path. Thus (A) is true, and (B) follows from Theorem 2.10 and the induction hypothesis.

**Case 2.** $G'$ does not have a cut-vertex: Since $G'$ has more than one cycle and $G'$ does not have a cut-vertex, $G'$ has two cycles that intersect in one path on at least two vertices or that intersect in more than one path. Then by Lemma 2.11, $G'$ has two cycles that intersect in one path on at least two vertices. Since $G' \in \mathcal{K}$, by Lemma 2.12, $G'$ has a subdivided chordal path, so (A) is true. Statement (B) then follows from Theorem 2.10 and the induction hypothesis.
Since the parameters $M$ and $Z$ sum over connected components, the result for every $G \in \mathcal{K}$ that does not have a cut-edge follows from the result for connected graphs.

Since $\mathcal{K}$ includes all complete subdivision graphs of simple graphs and multigraphs, we have the following corollary.

\textbf{Corollary 2.17.} If $G$ is a simple graph or multigraph that does not have a cut-edge, then $M(F, \overline{G}) = Z(\overline{G})$.

\section{Zero forcing number and maximum nullity of edge subdivision graphs.}

Recall that in [3], the authors ask the following question: Suppose $G$ is any graph in which each vertex has degree at least 3 and $H$ is a graph that has one less edge subdivision than $\overline{G}$. Is it always the case that $M(H) < M(\overline{G})$? The graphs $G$ and $H$ given in Example 3.1 below provide a negative answer to this question. We use the following well known observation: If $G = \bigcup_{i=1}^{k} G_i$, $G_i = (V_i, E_i)$, and $(F$ is infinite or $E_i \cap E_j = \emptyset$ for $i \neq j$), then $\text{mr}(F, G) \leq \sum_{i=1}^{k} \text{mr}(F, G_i)$.

\begin{figure}[h]
\centering
\includegraphics[width=0.3\textwidth]{graph.png}
\caption{A graph $G$ that provides negative answer to Question 3.1.}
\end{figure}

\textbf{Example 3.1.} Let $G$ be the graph in Figure 3.1 which is the connected union of three copies of $K_4$ (the complete graph on four vertices) and the star graph $K_{1,3}$, with these graphs having no common edges and the copies of $K_4$ disjoint; the edge $e$ is one of the edges of the $K_{1,3}$. Let $H$ be the graph that has one less edge subdivision than $\overline{G}$ where the edge $e$ in $G$ is the only unsubdivided edge. The graphs $\overline{G}$ and $H$ are shown in Figure 3.2.

Since $K_4$ has a Hamiltonian path, by Theorem 1.5 $\text{mr}(F, K_4) = 6$. The subgraph $K_{1,3}$ is a tree. Hence, by Theorem 1.4 $M(F, \overline{K_{1,3}}) = P(K_{1,3}) = 2$, so $\text{mr}(F, K_{1,3}) = 5$. Let $L$ be the graph obtained from $K_{1,3}$ by subdividing all but one edge; again by Theorem 1.4 $M(F, L) = P(L) = 2$ and so $\text{mr}(F, L) = 4$. Since $\overline{G}$ is a union of three
Zero Forcing, Maximum Nullity, and Path Covers of Subdivided Graphs

 copies of $K_4$ and one copy of $K_{1,3}$,

$$\text{mr}(F, \overline{G}) \leq 3 \text{mr}(F, \overline{K_4}) + \text{mr}(F, K_{1,3}) = 23 \quad \text{and} \quad M(F, \overline{G}) \geq 34 - 23 = 11.$$ 

Similarly, $H$ is a union of three copies of $K_4$ and one copy of $L$ so

$$\text{mr}(F, H) \leq 3 \text{mr}(F, \overline{K_4}) + \text{mr}(F, L) = 22 \quad \text{and} \quad M(F, H) \geq 33 - 22 = 11.$$ 

Furthermore, zero forcing sets of order 11 for both $\overline{G}$ and $H$ are exhibited in Figure 3.2. Therefore, $M(F, H) = Z(H) = M(F, \overline{G}) = Z(\overline{G}) = 11$.

Given that we conjecture $M(F, \overline{G}) = Z(\overline{G})$ for every field $F$ and graph $G$, one might be tempted to think that subdividing an edge cannot increase the difference $Z(G) - M(F, G)$. The next example shows that this is not the case. In fact, $M(F, G) = Z(G)$ does not necessarily imply $M(F, G_e) = Z(G_e)$.

**Example 3.2.** The pentasun $H_5$ is a five cycle with a degree one neighbor attached to each cycle vertex, shown in Figure 3.3(a). The graph $G$ in Figure 3.3(b) is obtained from $H_5$ by adding two degree one neighbors of $u$, where $u$ is a vertex of degree one in $H_5$. Note the labeled edge $e = uv$; the result $G_e$ of subdividing edge $e$ is shown in Figure 3.3(c). We show that $M(F, G) = Z(G)$ but $M(F, G_e) < Z(G_e)$.

It is well known that $M(F, H_5) = 2$, $M(F, H_5 - u) = 2$, $Z(H_5) = 3$, and $Z(H_5 - u) = 2$. Let $G' := G_e$. The maximum nullity of $G$ and $G'$ can be obtained by performing cut-vertex reduction using vertex $v$. Let $W_1$ (respectively, $W_1'$) be the vertices in the component of $G - v$ (respectively, $G'$) containing $u$ and let $W_2$ (respectively, $W_2'$) be the vertices of the other component. For $i = 1, 2$, let $G_i = G[W_i \cup \{v\}]$ and $G_i' = G[W_i' \cup \{v\}]$. So, $\text{mr}(F, G_1) = 2$, $\text{mr}(F, G[W_1]) = 2$, $\text{mr}(F, G_2) = 7$, $\text{mr}(F, G[W_2]) = 6,$
mr(F, G_1') = 3, mr(F, G'[W_1']) = 2, mr(F, G_2') = 7, and mr(F, G'[W_2']) = 6. Thus, 

\[ \text{mr}(F, G) = \sum_{i=1}^{2} \text{mr}(F, G[W_i]) + \min\{2, \sum_{i=1}^{2} r_v(F, G_i)\} = 9 \text{ so } M(F, G) = 12 - 9 = 3 \]

and

\[ \text{mr}(F, G') = \sum_{i=1}^{2} \text{mr}(F, G'[W_i']) + \min\{2, \sum_{i=1}^{2} r_v(F, G'_i)\} = 10 \]

so

\[ M(F, G_e) = M(F, G') = 13 - 10 = 3. \]

Zero forcing sets of size 3 for G and 4 for G_e are exhibited in Figures 3.3(b) and 3.3(c), and it is not difficult to see that no smaller sets can force. Thus M(F, G) = Z(G) = 3 and M(F, G_e) = 3 < Z(G_e) = 4. Zero forcing number and maximum nullity can also be computed by the minimum rank software [4].

It is easy to see that there is no relationship between the change in maximum nullity and the change in zero forcing number of G and G_e. In Example 3.2 edge subdivision increased zero forcing number but not maximum nullity. Subdividing any cycle edge of the pentasun H_5 increases maximum nullity but not zero forcing number (this follows from Proposition 2.1).

4. Path cover number of edge subdivision graphs. In this section we investigate the effects of edge subdivisions on the path cover number.

Proposition 4.1. Let G be a graph and e an edge of G. Then

\[ P(G) \leq P(G_e) \leq P(G) + 1. \]

If there exists a minimum path cover P of G such that e is on a path in P, then P(G_e) = P(G).
Proof. Let $e = uv$ and let $w$ be the new vertex in $G_e$ that is adjacent to $u$ and $v$. We first prove the upper bounds. Let $P = \{P_1, \ldots, P_k\}$ be a minimum path cover of $G$. If $e$ is in a path $Q = P_i$ for some $i = 1 \ldots k$, then $(P \setminus \{Q\}) \cup \{Q_e\}$ is a path cover of $G_e$, and so $P(G_e) \leq P(G)$. If $e$ is not in any $P_i$, then $P \cup \{w\}$ is a path cover of $G_e$. In either case, $P(G_e) \leq P(G) + 1$.

To prove the lower bound on $P(G_e)$, let $P = \{P_1, \ldots, P_k\}$ be a minimum path cover of $G$. Then $w \in P_i$ for some $i$. If $\{w\} = P_i$, then $P \setminus \{P_i\}$ is a path cover of $G$. If $w$ is an endpoint of $P_i \neq \{w\}$, define $P'_i$ to be the path obtained from $P_i$ by removing $uw$ and $wv$, and then adding the edge $uv$. Then $(P \setminus \{P_i\}) \cup \{P'_i\}$ is a path cover of $G$. In all cases, $P(G_e) \leq P(G)$.

Proposition 4.2. Let $G$ be a graph and let $e$ be an edge of $G$. If $e$ is incident to a vertex of degree at most 2, then $P(G_e) = P(G)$.

Proof. By Proposition 4.1, $P(G) \leq P(G_e)$. Now it remains to show that $P(G_e) \leq P(G)$. Without loss of generality, let $P = \{P_1, \ldots, P_k\}$ be a minimum path cover of $G$. If $e$ is on some path $P_i$ in $P$, then by Proposition 4.1, $P(G_e) = P(G)$. If $e$ is not in any $P_i$, then $u$ is the endpoint of some path in $P$. Without loss of generality, say $u$ is in $P_i$, then let $P'_i$ be the path obtained by adding $w$ to $P_i$. Then $(P \setminus \{P_i\}) \cup \{P'_i\}$ is a path cover of $G_e$. In either case, $P(G_e) \leq P(G)$.

It is conjectured that for all graphs $G$, $M(F, \overline{G}) = Z(\overline{G})$. The following is an example of a graph $G$ with $P(\overline{G}) < Z(\overline{G})$.

Example 4.3. Let $G$ be the graph pictured in Figure 4.1, called a double triangle. Since $G$ contains a Hamiltonian path, by Theorem 1.9, $Z(\overline{G}) = M(F, \overline{G}) = 3$. However, $P(\overline{G}) = 2$ because $\overline{G}$ is not a path and a path cover of order 2 is exhibited in Figure 4.1.

Fig. 4.1: A double triangle and its complete subdivision graph.
