ERROR PROPAGATION FORMULA OF MULTI-LEVEL ITERATIVE
AGGREGATION-DISAGGREGATION METHODS
FOR NON-SYMMETRIC PROBLEMS

IVANA PULTAROVÁ

Abstract. Iterative aggregation-disaggregation methods for numerical computing of stationary
probability distribution vectors of stochastic matrices are studied. The methods can use arbitrary
numbers of levels and of smoothing steps. A formula for the error propagation is derived. Using this
formula, some asymptotic convergence properties of these methods for non-symmetric problems are
demonstrated.

1. Introduction. Multi-level solution methods are considered as an advanta-
geous technique in numerical mathematics. Multi-level and multi-grid methods are
popular mainly in numerical solutions of partial differential equations. In this pa-
per we study iterative aggregation-disaggregation (IAD) methods for computing sta-
tionary probability distribution vectors of finite discrete Markov chains. A growing
interest in this field is motivated by many large scale applications in information tech-
nology, data mining, biology, safety and reliability computation, and other theoretical
and practical disciplines.

Basics of the IAD methods are found in Stewart’s book [9]. Many papers show
an efficient performance of the IAD methods, see e.g. [1] [2] [3] and the references
therein. However, theoretical results are rare: only some convergence conditions for
are available.

It appears that for non-symmetric problems, the multi-level methods do not pos-
sess the appropriate properties as in the case of symmetric problems [8]. Our paper
focuses on some rules which could be expected for the IAD methods, but which do

not hold. As a main tool, we introduce a new formula for an error propagation matrix of the IAD methods with an arbitrary number of levels. While in our recent paper \cite{Pultarová2012} we started this study by the derivation of an error propagation formula for the IAD methods without pre-smoothing steps, in this paper we deal with more general IAD methods with arbitrary numbers of pre-smoothing steps and of post-smoothing steps in every level.

The paper is organized as follows. In Section 2, the notation and description of the IAD method are introduced. Section 3 is the main part of the paper. Since a formula for the error propagation matrix of a general multi-level IAD method is rather complicated, we present it only for a three-level method with an arbitrary number of smoothing steps (Theorem 3.1) and for a method with an arbitrary number of levels but with exactly one pre-smoothing step and one post-smoothing step in every level (Theorem 3.2). Simple examples are presented in Section 4 to confirm the absence of several relations which could seem natural for the multi-level IAD methods. Conclusion and one open question are found in Section 5.

2. Notation and description of the IAD methods. Let us assume that $B$ is an irreducible stochastic matrix. This means that $B$ has non-negative elements, the sum of the elements in each column is equal to unity, and there does not exist any symmetric permutation of the columns and rows of $B$ such that the resulting permuted matrix $\tilde{B}$ admits a block form

$$\tilde{B} = \begin{bmatrix} \tilde{B}_{11} & \tilde{B}_{12} \\ 0 & \tilde{B}_{22} \end{bmatrix},$$

where the diagonal blocks $\tilde{B}_{11}$ and $\tilde{B}_{22}$ are square. Let $e$ denote a column vector of ones of an appropriate size. From the Perron-Frobenius theorem \cite{PerronFrobenius1926}, $B$ has a unique eigenvalue of modulus 1 and there exists a unique positive eigenvector $\hat{x}$ for which $B\hat{x} = \hat{x}$ and $e^T \hat{x} = 1$. Vector $\hat{x}$ is called a stationary probability distribution vector of the matrix $B$. Let us define $P = \hat{x}e^T$ and $Z = B - P$. It is obvious that $P^2 = P$ and that $PZ = ZP$ is a null matrix.

Many iterative methods can be exploited for computing the eigenvector $\hat{x}$, for example, the power method, Jacobi method, Gauss-Seidel method or their block modifications. We will study a multi-level approach which is called an iterative aggregation-disaggregation (IAD) method.

Let us denote by $L$ the number of levels used within the method. The original (finest, largest) problem belongs to level $m = 1$ and the coarsest (smallest) problem is solved in level $m = L$. In every level up to the coarsest one, aggregation groups $G_{mj}$ of indices of elements are chosen, where $m = 1, 2, \ldots, L - 1$ and $j = 1, 2, \ldots, N_{m+1}$. Thus $N_{m+1}$ is the number of aggregation groups in level $m$ and at the same time it is
the number of elements in level $m + 1$ for $m = 1, 2, \ldots, L - 1$. The size of the original matrix $B$ is $N_1$ and the size of the coarsest problem solved is $N_L$.

Without loss of generality, we suppose that in every level $m = 1, 2, \ldots, L - 1$, the indices are divided into groups in such a manner that from $i_1 \in G_{k_1}$, $i_2 \in G_{k_2}$ and $i_1 < i_2$, it follows that $k_1 < k_2$. In other words, smaller indices fall into groups with smaller indices.

Let us denote by $[A]_{ij}$ an element of a matrix $A$ in row $i$ and column $j$. Transitions between levels are enabled by reduction and prolongation matrices. Reduction matrices $R_m$ map from $\mathbb{R}^{N_m}$ into $\mathbb{R}^{N_{m+1}}$,

$$[R_m]_{ij} = \begin{cases} 1 & \text{if } j \in G_{mi} \\ 0 & \text{otherwise.} \end{cases}$$

Prolongation matrices $S(x)_m$ map from $\mathbb{R}^{N_{m+1}}$ into $\mathbb{R}^{N_m}$ depending on a positive vector $x \in \mathbb{R}^{N_m}$,

$$[S(x)_m]_{ij} = \begin{cases} x_i \sum_{k \in G_{mj}} x_k & \text{if } i \in G_{mj}, \\ 0 & \text{otherwise.} \end{cases}$$

In every level $m = 1, 2, \ldots, L - 1$, some smoothing steps are performed before and after the solution of the coarser problem of level $m + 1$. The smoothing steps, also called basic iterations, are represented by the power method in our algorithm.

A single cycle of the multi-level IAD algorithm can be described as follows. A constant $\tau$ is a threshold for the size of problems the solution of which is carried out exactly.

$$\text{Procedure IAD (input: } B, x; \text{ output: } y)$$

if $\text{size}(B) < \tau$ solve $By = y$, $e^T y = 1$;
else
  $x := B^\mu x$;
  build $R$ and $S(x)$ according to aggregation groups in a current level;
  call Procedure IAD (input: $RBS(x)$, $Rx$; output: $y$);
  $y := B^\nu S(x)y$.

In the main program the procedure is first called with the input parameters $B$, the original irreducible non-negative matrix, and $x$ as an initial approximation to $\hat{x}$. One cycle of the IAD method is represented by one call of this procedure in the original level. After every cycle, $y$ is assigned to $x$ and next cycle is performed. The procedure is executed until the difference between $x$ and $y$ in the finest level is sufficiently small.

Let $\mu_m$ and $\nu_m$ denote the numbers of smoothing steps in level $m$ before and after the coarsening of the problem, respectively. Using this notation we can describe
a single multi-level cycle of the IAD algorithm. Let \( x_n \) be a current approximation to the solution \( \hat{x} \). Then the next cycle of the IAD procedure yields \( x_{n+1} \) in the form

\[
x_{n+1} = B^{\nu_1} S(u_1) v_2,
\]

where

\[
u_1 = B^{\mu_1} x_n,
\]

\[
u_m = (R_{m-1} \cdots R_1 BS(u_1) \cdots S(u_{m-1}^{-1}m^{-1}))^{\nu_m} R_{m-1} u_{m-1},
\]

\[
u_m = (R_{m-1} \cdots R_1 BS(u_1) \cdots S(u_{m-1}^{-1}m^{-1}))^{\nu_m} S(u_m) v_{m+1}
\]

for \( m = 2, 3, \ldots, L - 1 \). Vector \( v_L \) is the exact solution of the coarsest problem \( T_L x = x \), where \( T_L \) is

\[
T_L = R_{L-1} \cdots R_1 BS(u_1) \cdots S(u_{L-1}^{-1}L^{-1}).
\]

The vectors \( u_k \) are computed during the coarsening process (the first half of a single multi-level IAD cycle) while the vectors \( v_k \) are computed during the returning back to finer levels (the second half of a single IAD cycle).

Let the identity matrix be denoted by \( I \). Let \( T = A_1^{-1} A_2 \) come from some regular splitting [10] of \( A_1 - A_2 = I - B, A_1^{-1} \geq 0, A_2 \geq 0 \). Thus \( T \hat{x} = \hat{x} \). In addition, let \( TB = BT \). Then the iteration matrices in levels \( m = 1, 2, \ldots, L - 1 \)

\[
B_m = R_{m-1} \cdots R_1 BS(u_1) \cdots S(u_{m-1}^{-1}m^{-1})
\]

can be substituted by the more general

\[
T_m = R_{m-1} \cdots R_1 TS(u_1) \cdots S(u_{m-1}^{-1}m^{-1})
\]

This generalization will be used in theorems in Section 3. The matrix \( T \) can vary during the computation process. However, for simplicity’s sake, we will not consider variable \( T \), and, in our numerical examples, only \( T = B \) will be used. In the coarsest level, \( T \neq B \) could be used, but then the definitions of matrices \( R_m \) and \( S(x) \) would need to be changed. This is why we have used only \( T_L = B_L \) in the coarsest level.

**Lemma 2.1.** The iteration matrices

\[
T_m = R_{m-1} \cdots R_1 TS(u_1) \cdots S(u_{m-1}^{-1}m^{-1}),
\]

\( m = 1, 2, \ldots, L \), are non-negative and irreducible. If \( T = B \) then \( T_m \) is stochastic.

**Proof.** We have \( T \geq 0 \) and thus \( T_m \geq 0 \) yields from the definitions of \( R_m \) and of \( S(x) \). The irreducibility follows from the irreducibility of \( T \). From \( e^T B = e^T \) we obtain \( e^T B_m = e^T \). QED
IAD methods for non-symmetric problems

Let us denote
\[ P(u_k, u_{k+1}, \ldots, u_{m-1})_{km} = S(u_k)_k \cdots S(u_{m-1})_{m-1}R_{m-1} \cdots R_k, \]
where \( u_j \) are positive vectors and \( u_j \in \mathbb{R}^{N_j}, j = k, \ldots, m - 1 \). During the proofs in Section 3 we will use the abbreviation \( P_m \equiv P(u_1, u_2, \ldots, u_{m-1})_{1m} \) and \( P_1 = I \).

**Lemma 2.2.** The following two relations hold.

1. For any positive \( x \in \mathbb{R}^{N_k} \) we have \( S(x)_kR_kx = x \).
2. Matrices \( P(u_k, u_{k+1}, \ldots, u_{m-1})_{km} \) are projections, for \( 1 \leq k < m \leq L \).

*Proof.* The first part follows from the definition of \( R_k \) and \( S(x)_k \). The second part follows from \( R_jS(x)_j = I, j = 1, \ldots, L - 1 \). \( \Box \)

**3. Error propagation formulae.** In this section we introduce our main results. We derive the error propagation matrices of the IAD methods described in Section 2. Due to the complexity of the involved terms, we restrict ourselves to two cases: (i) three levels of hierarchy, \( L = 3 \), and arbitrary numbers of pre-smoothing steps and of post-smoothing steps, i.e. arbitrary \( \mu_m \) and \( \nu_m \) in both levels \( m = 1, 2 \); and (ii) arbitrary number \( L \) of levels and exactly one pre-smoothing step and one post-smoothing step in every level, i.e. \( \mu_m = \nu_m = 1, m = 1, 2, \ldots, L - 1 \). Deriving the error propagation matrices for these two kinds of methods within proofs of the following two theorems shows the main ideas and tools which can be used for deducing error propagation formulae for more complicated methods.

**Theorem 3.1.** Let us consider a three-level IAD method, \( L = 3 \), with \( \mu_m + \nu_m \geq 1, m = 1, 2 \). The error in cycle \( n \) is
\[ x_{n+1} - \hat{x} = J(x_n)(x_n - \hat{x}). \]
Let us denote \( u_1 = T^{\mu_1}x_n, u_2 = (R_1TS(u_1))^{\mu_2}R_1u_1, P_1 = I, P_2 = S(u_1)_1R_1, \) and \( P_3 = S(u_1)_1S(u_2)_2R_2R_1 \).

1. If \( \mu_2 \geq 1 \) and \( \nu_2 \geq 1 \) then
\[
J(x_n) = T^{\nu_1}(P_2T)^{\nu_2}(I - P_3Z)^{-1}P_2 \sum_{k=0}^{\mu_2-1} (TP_2)^k(T - I) + I - P_3
\]
\[
+ \sum_{k=0}^{\nu_2-1} (P_2T)^k(I - P_2) \bigg)T^{\mu_1}.
\]
2. If \( \mu_2 \geq 1 \) and \( \nu_2 = 0 \) then
\[
J(x_n) = T^{\nu_1}(I - P_3Z)^{-1}P_2 \sum_{k=0}^{\mu_2-1} (TP_2)^k(T - I) + I - P_3)T^{\mu_1}.
\]
Thus we have

\[ T^{\nu_1} \left( (P_2T)^{\nu_2} (I - P_3Z)^{-1} (I - P_3) + \sum_{k=0}^{\nu_2-1} (P_2T)^k (I - P_2) \right) T^{\mu_1}. \]

**Proof.** We start with a proof of the first assertion for \( \mu_2 \geq 1 \) and \( \nu_2 \geq 1 \). Let us follow the computation during a single cycle of the considered IAD method. First \( u_1 \) is computed, \( u_1 = T^{\mu_1}x_n \). Then this vector is reduced and multiplied by \( (R_1TS(u_1))^{\nu_2} \), and thus

\[ u_2 = (R_1TS(u_1))^{\mu_2} R_1u_1 = (R_1TS(u_1))^{\nu_2} R_1T^{\mu_1}x_n. \]

In the third level, the computation of the eigenvector \( v_3 \) of the reduced matrix is carried out exactly for \( T = B \),

\[ R_2R_1BS(u_1)S(u_2)v_3 = v_3, \]

and \( e^Tv_3 = 1 \). None of the eigenvalues of \( R_2R_1ZS(u_1)S(u_2) \) are equal to unity, and

\[ v_3 = (I - R_2R_1ZS(u_1)S(u_2))^{-1} R_2R_1\hat{x}. \]

On the way back to the finest level, the vector \( v_3 \) is prolonged by a multiplication by \( S(u_2)^T \) to level \( m = 2 \) and then multiplied by the iteration matrix \( (R_1TS(u_1))^{\nu_2} \) in level \( m = 2 \),

\[ v_2 = (R_1TS(u_1))^{\nu_2} S(u_2)v_3. \]

And finally,

\[ x_{n+1} = v_1 = T^{\nu_1}S(u_1)^Tv_2. \]

Thus we have

\[ x_{n+1} - \hat{x} = T^{\nu_1}S(u_1)^T(R_1TS(u_1))^{\nu_2} S(u_2)^T(I - R_2R_1ZS(u_1)S(u_2))^{-1} R_2R_1\hat{x} - \hat{x} \]

\[ = T^{\nu_1}(P_2T)^{\nu_2}(I - P_3Z)^{-1} P_3\hat{x} - \hat{x}. \]

Now we can rewrite the term \( P_3\hat{x} \) using Lemma 2.2:

\[ P_3\hat{x} = S(u_1)^T S(u_2)^T R_2(R_1\hat{x} - u_2 + u_2) \]

\[ = S(u_1)^T S(u_2)^T R_2(R_1\hat{x} - u_2) \]

\[ = S(u_1)^T S(u_2)^T R_2(R_1\hat{x} - u_2) \]

\[ = S(u_1)^T S(u_2)^T R_2(R_1\hat{x} + S(u_1)^T S(u_2)^T R_2(R_1\hat{x}) \]

\[ - (R_1TS(u_1))^{\nu_2} R_1T^{\mu_1}x_n \]

\[ = P_2(TP_2)^{\nu_2} T^{\mu_1}x_n + P_3(\hat{x} - (TP_2)^{\nu_2} T^{\mu_1}x_n). \]
IAD methods for non-symmetric problems

Using $P_T T^{\mu_1} x_n = T^{\mu_1} x_n$ and $T \hat{x} = \hat{x}$, the term $(T P_T) T^{\mu_1} x_n$ is

\[
(T P_T) T^{\mu_1} x_n = (T P_T) T^{\mu_2-1} (T P_T T^{\mu_1} x_n - T T^{\mu_1} \hat{x} + T^{\mu_1} \hat{x} - T \hat{x} + T \hat{x}) \\
= (T P_T) T^{\mu_2-1} (T T^{\mu_1} x_n - T T^{\mu_1} \hat{x} + T^{\mu_1} x_n - T^{\mu_1} x_n) \\
= (T P_T) T^{\mu_2-1} (T - I) T^{\mu_1} (x_n - \hat{x}) + (T P_T) T^{\mu_2-1} T^{\mu_1} x_n \\
= \ldots \\
= (T P_T) T^{\mu_2-1} + \ldots + (T P_T) (T - I) T^{\mu_1} (x_n - \hat{x}) \\
+ T T^{\mu_1} (x_n - \hat{x}) + \hat{x},
\]

which yields

\[
\hat{P} \hat{x} = (P_T - P) (\{(T P_T) T^{\mu_2-1} + \ldots + T P_T + I\} (T - I) + I) T^{\mu_1} (x_n - \hat{x}) + P_T \hat{x}.
\]

We also have

\[
P_T \hat{x} = S(u_1) R_1 \hat{x} = S(u_1) R_1 (\hat{x} - u_1 + u_1) = u_1 + P_T (\hat{x} - u_1) =
\]

\[
= T^{\mu_1} x_n + P_T T^{\mu_1} (x_n - \hat{x}) = (I - P_T) T^{\mu_1} (x_n - \hat{x}) + \hat{x}.
\]

Then

\[
x_{n+1} - \hat{x} = T^{\nu_1} (P_T T)^{\nu_2} (I - P_T Z)^{-1} \left( (P_T - P) \left( \{(T P_T) T^{\mu_2-1} + \ldots + T P_T + I\} (T - I) + I \right) T^{\mu_1} (x_n - \hat{x}) \right) \\
+ (I - P_T) T^{\mu_1} (x_n - \hat{x}) + \hat{x} \\
= T^{\nu_1} (P_T T)^{\nu_2} (I - P_T Z)^{-1} \left( (P_T - P) \left( \{(T P_T) T^{\mu_2-1} + \ldots + T P_T + I\} (T - I) + I \right) + (I - P_T) \right) T^{\mu_1} (x_n - \hat{x}) \\
+ T^{\nu_1} (P_T T)^{\nu_2} \hat{x} - \hat{x}.
\]

Exploiting similar tools as in (3.1) we can show that

\[
T^{\nu_1} (P_T T)^{\nu_2} \hat{x} - \hat{x} = T^{\nu_1} (P_T T)^{\nu_2-1} + \ldots + I) (I - P_T) T^{\mu_1} (x_n - \hat{x})
\]

Combining (3.2) and (3.3) we get the first part of the theorem. The second one can be easily derived using a similar technique. Using either similar tools as for the previous parts or Theorem 2 of paper [1] yields the third part of the theorem.\]

**Theorem 3.2.** The error in cycle $n$ of a multi-level IAD method with an arbitrary number $L \geq 2$ of levels and with one pre-smoothing step and one post-smoothing step in every level (that is $\mu_m = \nu_m = 1$ for $m = 1, 2, \ldots, L - 1$) is

\[
x_{n+1} - \hat{x} = J(x_n) (x_n - \hat{x}),
\]
where

(a) 
\[ J(x_n) = T \prod_{k=2}^{L-1} (P_kT)(I - P_kZ)^{-1} \sum_{k=1}^{L-1} (P_k - P_{k+1})M_{k-1} \]
\[ + T \sum_{m=1}^{L-2} \prod_{k=2}^{m} (P_kT) \sum_{k=1}^{m} (P_k - P_{k+1})M_{k-1}; \]

(b) 
\[ M_0 = T \text{ and} \]
\[ M_k = (T + \sum_{j=2}^{k} TP_j(T - I))T, \]

for \( k = 1, 2, \ldots, L - 2; \)

(c) 
\[ P_1 = I \text{ and} \]
\[ P_k = P(u_1, u_2, \ldots, u_{k-1})_{1k} = S(u_1)_1 \cdots S(u_{k-1})_{k-1} R_{k-1} \cdots R_1, \]

for \( k = 2, 3, \ldots, L; \)

(d) 
\[ u_1 = Tx_n, \ u_2 = R_1T^2x_n, \ u_3 = R_2R_1TP_2T^2x_n \text{ and}
\]
\[ u_k = R_{k-1} \cdots R_1TP_{k-1}TP_{k-2} \cdots TP_3TP_2T^2x_n, \]

for \( k = 4, \ldots, L - 1. \)

**Proof.** We present the derivation of the formula only for \( L = 5 \) which is not too much complicated but provides with a sufficiently general insight. We have

\[ u_1 = Tx_n, \]
\[ u_2 = R_1TS(u_1)_1R_1u_1 = R_1T^2x_n, \]
\[ u_3 = R_2R_1TS(u_1)_1S(u_2)_2R_2u_2 = R_2R_1TS(u_1)_1u_2 = R_2R_1TS(u_1)_1R_1T^2x_n \]
\[ = R_2R_1TP_2T^2x_n, \]
\[ u_4 = R_3R_2R_1TS(u_1)_1S(u_2)_2S(u_3)_3R_3u_3 = \cdots = R_3R_2R_1TP_3TP_2T^2x_n. \]

Since from Lemma 2.2 we have \( S(u_k)_kR_ku_k = u_k, \ k = 1, \ldots, 4, \) note that

\[ (3.4) \quad P_2Tx_n = Tx_n, \]
\[ (3.5) \quad P_3T^2x_n = P_2T^2x_n, \]
\[ (3.6) \quad P_4TP_2T^2x_n = P_3TP_2T^2x_n, \]
\[ (3.7) \quad P_5TP_3TP_2T^2x_n = P_4TP_3TP_2T^2x_n. \]
In the fifth (finest) level, the computation of the eigenvector is carried out exactly with $T = B$,

$$R_4R_3R_2R_1BS(u_1)_1S(u_2)_2S(u_3)_3S(u_4)_4v_5 = v_5,$$

$e^Tv_5 = 1$. Matrix $I - R_4\cdots R_1ZS(u_1)_1\cdots S(u_4)_4$ is invertible, therefore

$$v_5 = (I - R_4\cdots R_1ZS(u_1)_1\cdots S(u_4)_4)^{-1}R_4\cdots R_1\hat{x}.$$

Further computation in finer levels gradually yields

$$v_4 = R_3R_2R_1TS(u_1)_1S(u_2)_2S(u_3)_3S(u_4)_4v_5,$$
$$v_3 = R_2R_1TS(u_1)_1S(u_2)_2S(u_3)_3v_4,$$
$$v_2 = R_1TS(u_1)_1S(u_2)_2v_3,$$
$$x_{n+1} = v_1 = TS(u_1)_1v_2.$$

Then

$$x_{n+1} - \hat{x} = TP_2TP_3TP_4(T-I-P_5Z)^{-1}P_5\hat{x} - \hat{x}.$$

Using (3.4)(3.7) we have

$$P_5\hat{x} = P_5(\hat{x} - TP_3TP_2T^2x_n) + P_1TP_3TP_2T^2x_n$$

and

$$TP_2TP_2T^2x_n = (TP_2TP_2(T-I)T + TP_2(T-I)T + T^2)(x_n - \hat{x}) + \hat{x} = M_3(x_n - \hat{x}) + \hat{x},$$

where $M_3 = TP_2(T-I)T + TP_2(T-I)T + T^2$. Thus

$$P_5\hat{x} = (P_4 - P_5)M_3(x_n - \hat{x}) + P_4\hat{x}.$$

Computing $P_4\hat{x}$ and $P_5\hat{x}$ in a similar fashion, we obtain

$$P_4\hat{x} = (P_1 - P_4)M_2(x_n - \hat{x}) + P_3\hat{x},$$
$$P_3\hat{x} = (P_2 - P_3)M_1(x_n - \hat{x}) + P_2\hat{x},$$
$$P_2\hat{x} = (I - P_2)M_0(x_n - \hat{x}) + \hat{x},$$

where $M_2 = TP_2(T-I)T + T^2$, $M_1 = T^2$ and $M_0 = T$. Thus we have

$$P_5\hat{x} = \left(\left((P_4 - P_5)M_3 + (P_3 - P_4)M_2 + (P_2 - P_3)M_1 + (I - P_2)M_0\right)(x_n - \hat{x}) + \hat{x}\right) + \hat{x}.$$

Substituting this into (3.8), denoting $P_1 = I$ and using $Z\hat{x} = 0$, we get

$$x_{n+1} - \hat{x} = TP_2TP_3TP_4T(I - P_5Z)^{-1}\left(\left((P_4 - P_5)M_3 + (P_3 - P_4)M_2 + (P_2 - P_3)M_1 + (I - P_2)M_0\right)(x_n - \hat{x}) + \hat{x}\right) - \hat{x}$$

$$= TP_2TP_3TP_4T(I - P_5Z)^{-1}\left(\sum_{k=1}^{4}(P_k - P_{k+1})M_{k-1}\right)(x_n - \hat{x}) + TP_2TP_3TP_4T\hat{x} - \hat{x}.$$
Finally, using (3.9)-(3.11), we obtain
\[
TP_2TP_3T\hat{x} - \hat{x} = TP_2TP_3\left((P_3 - P_4)M_2 + (P_2 - P_3)M_1\right)
+ (P_1 - P_2)M_0(x_n - \hat{x})
+ TP_2\left((P_2 - P_3)M_1 + (P_1 - P_2)M_0\right)(x_n - \hat{x})
+ T(P_1 - P_2)M_0(x_n - \hat{x}).
\]
Substituting this last formula into (3.12) completes the proof. \(\square\)

Example 3.3. Assume a three-level IAD method, \(L = 3\), and three simple choices of parameters \(\mu_k\) and \(\nu_k\). According to both Theorems 3.1 and 3.2 for \(\mu_1 = \mu_2 = \nu_1 = \nu_2 = 1\) the error propagation matrix \(J\) is
\[
J = TP_2(T(I - P_3Z)^{-1}((P_2 - P_3)T + I - P_2)T + T(I - P_2)T).
\]
When we chose \(\mu_1 = \mu_2 = 0\) and \(\nu_1 = \nu_2 = 2\), from Theorem 3.1 we obtain
\[
J = T^2((P_2T)^2(I - P_3Z)^{-1}(I - P_3) + (I + P_2T)(I - P_2)).
\]
When we chose \(\mu_1 = \mu_2 = 2\) and \(\nu_1 = \nu_2 = 0\), from Theorem 3.1 we have
\[
J = (I - P_3Z)^{-1}((P_2 - P_3)(I + TP_2)(T - I) + I - P_3)T^2.
\]

4. Symmetric and non-symmetric matrices. In this part we will exploit the 8 \(\times\) 8 non-symmetric irreducible stochastic matrix
\[
B = \begin{bmatrix}
\epsilon & 1 & 0 & 0 & 0 & 0 & 0 & \beta \\
0 & 0 & \delta + \zeta & 1 & \alpha & \delta & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & \alpha + \gamma & \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & \\
\zeta & 0 & \beta & 0 & 1 & \gamma & 0 & 0 & \\
\delta & 0 & 0 & 0 & 0 & 1 & \epsilon
\end{bmatrix}.
\]
We apply the multi-level IAD methods to the matrix \(B\) for several choices of parameters \(\alpha, \beta, \gamma, \delta, \epsilon\) and \(\zeta\). After setting the values of these parameters, the columns are normalized in such a way that the resulting matrix is stochastic.

Example 4.1. Consider the matrix \(B\) given by (4.1), \(L = 3\), \(N_1 = 8\), \(N_2 = 4\), \(N_3 = 2\) and the dimensions of aggregation groups equal to \(N_m/N_{m+1}\) in every level \(m\).
IAD methods for non-symmetric problems

Table 4.1
Spectral radii \( \rho(J(\hat{x})) \) for \( L = 3, N_1 = 8, N_2 = 4, N_3 = 2 \) and for matrix \( B \) defined by \( 4.1 \)
with different choices of \( \alpha, \beta, \gamma \).

We examine three choices of parameters \( \mu_k, \nu_k, k = 1, 2 \): (i) \( \mu_k = \nu_k = 1 \); (ii) \( \mu_k = 0, \nu_k = 2 \); (iii) \( \mu_k = 2, \nu_k = 0 \). See Table 4.1 for the approximate asymptotic spectral radii \( \rho(J(\hat{x})) \) of the error propagation matrices for \( \delta = \epsilon = \zeta = 0 \) and for different choices of \( \alpha, \beta, \gamma \). The spectral radii are calculated according to \( 3.13 \)-\( 3.15 \). In our paper \([7]\) the hypothesis appeared, that keeping the number of smoothing steps constant in all levels, i.e. \( \mu_k + \nu_k \) constant for every \( k \), leads to the same asymptotic convergence rate. It can be seen from the table that this hypothesis is false. Moreover, the convergence itself is also not kept for different \( \mu_k, \nu_k \), but constant \( \mu_k + \nu_k \).

**Example 4.2.** In this example we examine the IAD methods for the matrix \( B \) given by \( 4.1 \) where \( \alpha = \beta = \gamma = 0 \). We compare three types of methods: (i) a two-level method with \( N_2 = 4 \); (ii) a two-level method with \( N_2 = 2 \); (iii) a three-level method with \( N_2 = 4; N_3 = 2 \). The numbers of smoothing steps are “symmetric”: \( \mu_k = \nu_k = 1 \). Three choices of parameters \( \delta, \epsilon, \zeta \) lead to three different situations, when one of the methods diverges and the other ones converge locally. Thus there is no apparent relation between local convergence of the IAD algorithms of the same kind with different numbers of levels.

**Remark 4.3.** When a stochastic matrix \( B \) is symmetric or satisfies \( B = DSD^{-1} \) where \( S \) is symmetric and \( D \) is diagonal, then all of our numerical experiments have reflected that \( \rho(J(\hat{x})) \leq 1 \). Although the proof of this is known \([8]\) for two-level IAD methods, the statement for general multi-level IAD methods has not been proved yet.

**5. Conclusion.** New convergence characteristics of the multi-level IAD methods are introduced in this paper. Especially, we present an error propagation formula which is a generalization of our recent result \([7]\). Using the formula it can be confirmed
that the local convergence of the multi-level IAD methods is not guaranteed for non-symmetric problems in general.

The derivation of the error propagation formula can serve as a model: the tools of the proofs of Theorems 3.1 and 3.2 can be exploited to obtain error propagation formulae for more complicated multi-level IAD methods. For example, the formulae for arbitrary number of levels \(L\) and for arbitrary numbers of smoothing steps \(\mu_k\) and \(\nu_k\) in every level \(k = 1, 2, \ldots, L - 1\) can be derived. This can lead to the estimation of local convergence rates of particular methods for particular matrices which can help in searching general conditions under which the local convergence of the IAD methods for non-symmetric problems is guaranteed.

In paper [7], a new hypothesis was announced, that the asymptotic rate of convergence does not depend on the numbers of pre- and post-smoothing steps but depends solely on the sum of these two quantities. Example 4.1 disproves it. In Example 4.2 we give a counter-example of another hypothesis, which states that for \(\mu_k = \nu_k\), \(k = 1, 2, \ldots, L - 1\), there exists some relation between the local convergence of IAD with \(L\) levels and with \(L + 1\) levels.

Our numerical experiments support a new hypothesis: if a stochastic matrix \(B\) is symmetric or similar to a symmetric matrix \(S\) such that \(B = DSD^{-1}\) and \(D\) is diagonal, then the asymptotic spectral radius of the error propagation matrix is bounded from above by unity for an arbitrary number of levels and of smoothing steps and for any choice of aggregation groups. This hypothesis was proved for two-level IAD methods only [8], but for general multi-level IAD methods it has not been proved yet.
