STOCHASTIC FORMS OF NON-NEGATIVE MATRICES AND PERRON-REGULARITY*

RICARDO GÓMEZ†

Abstract. Given a real non-negative square matrix $A$, the problem of determining when two distinct constructions of stochastic matrices associated to $A$ coincide is studied. All the constructions (or stochastic forms) that are considered are diagonal forms, i.e., the transformations act like $A \mapsto \alpha D^{(r)} A D^{(c)}$, where $D^{(r)}$ and $D^{(c)}$ are diagonal matrices with positive diagonals and $\alpha > 0$, all depending on $A$.

Key words. Non-negative matrix, Stochastic form, Diagonal form, Tensor product, Perron-regular.

AMS subject classifications. 15B51, 05C81.

1. Introduction. There exist several distinct approaches to construct stochastic matrices of transition probabilities of discrete time (homogeneous) Markov chains. Usually a real non-negative square matrix $A$ indexed by the (finite) state space is given and then a certain normalization $f$ yields a stochastic matrix $f(A)$, a stochastic form of $A$. For example, a common standard procedure is to divide each non-zero entry of $A$ by the sum of the entries in the corresponding row [1, 3, 9, 10, 11, 15, 20, 25, 30, 33, 39, 40, 41, 42, 43] (this method is used very often on random walks on simple directed graphs, letting $A$ be the corresponding adjacency matrix). As another example, if a priori the Markov chain is known to be doubly stochastic, then one may be able to apply the well known Sinkhorn-Knopp construction to $A$ [8, 22, 24, 27, 28, 29, 35, 37, 38]. Brualdi, Parter and Schneider [8] have studied stochastic forms that result by multiplying the matrix $A$ from the left and the right by the same diagonal matrix $D$, $A \mapsto D A$. A final important example occurs when $A$ is irreducible [6, 12, 26, 31, 36]: If $(\lambda_A, p_A)$ is a right Perron eigenpair of $A$, then $\lambda_A^{-1} P_A^{-1} AP_A$ is stochastic, where $P_A$ is the diagonal matrix with $p_A$ in the main diagonal. Our main purpose here is to study when two different stochastic forms coincide. We will consider the four stochastic forms just mentioned and call them standard, Sinkhorn-Knopp, Brualdi-Parter-Schneider and Perron, respectively.

The paper is organized as follows. Section 2 starts with basic definitions and notation. Section 3 presents the stochastic forms and briefly surveys each case, stating well known results and proving basic facts that will be used later. Section 4 contains the main results of the paper which are concerned with conditions for two distinct stochastic forms to yield the same stochastic matrix, a property that we call stochastic regularity. We show that stochastic regularity is preserved under tensor products (for an account of this operation on Hilbert spaces see [31]). The proofs rely on direct computations as well as on applications of previous results; in particular, we systematically apply the Perron-Frobenius Theorem. A non-negative square irreducible matrix is called Perron-regular if its standard and Perron stochastic forms coincide (Theorem 4.3). This case deserves special attention because if \( A \) is the adjacency matrix of a strongly connected simple directed graph, then the Perron stochastic form yields the unique measure of maximal entropy [34], whereas the standard stochastic form is widely used, particularly in random walks on simple directed graphs. We give an algebraic characterization of Perron-regularity in terms of Perron vectors (Definition 4.7). In Section 5, we identify all the (weighted) Perron-regular graphs (Theorems 5.4 and 5.5), and also introduce and study Perron-regular degrees (roughly speaking, the Perron-regular degree measures the “degrees of freedom” imposed by the algebraic characterization of Perron-regularity, and Theorem 5.9 shows that it always attains its maximum possible value). We leave the following as an open problem.

**Problem 1.1.** Identify all the Perron-regular directed graphs.

Theorem 4.12 suggests that such an identification may be given as a decomposition into tensor products of “elementary” Perron-regular directed graphs (e.g. regular directed graphs). Also, the colonial digraph introduced in Section 5 may be useful in an inductive approach to Problem 1.1. Although we mainly focus on Perron-regularity, i.e. when the standard and the Perron stochastic forms coincide, the results presented in this paper may be seen as a basic set of tools to address this type of “regularity” problem. Other stochastic forms can be of interest like those coming from the Metropolis-Hastings algorithm [32] as well as transition probabilities defined in terms of square roots of vertex degrees [17].

Observe that the standard, Brualdi-Parter-Schneider and Perron stochastic forms admit each both row and column versions. The Sinkhorn-Knopp doubly stochastic form results by iterating the row and column versions of the standard stochastic form. It is therefore natural to ask what happens when iterating the row and column versions of both the Brualdi-Parter-Schneider and the Perron stochastic forms. This is addressed in Remarks 3.7 and 3.11.

2. Preliminaries. Let \( n \geq 1 \) be a positive integer and let \( [n] = \{1, \ldots, n\} \). The identity matrix of size \( n \) is denoted by \( I_n \). The column vector of size \( n \) whose entries
are all equal to 1 is denoted by \( J_n \), i.e., \( J_n^T = (1, \ldots, 1) = \{1\}^n \). Given a subset \( \Omega \subset \mathbb{R} \) of the real numbers, an \( \Omega \)-matrix is a matrix whose entries belong to \( \Omega \) (for example, \( \mathbb{R}^+ \)-matrices correspond to matrices with real non-negative entries). Let \( A = (A_{i,j})_{i,j=1}^n \) be a square \( \mathbb{R}^+ \)-matrix of size \( n \). \( A \) is row (resp., column) stochastic if \( AJ_n = J_n \) (resp., \( J_n^TA = J_n^T \)). \( A \) is doubly stochastic if it is both row and column stochastic. A diagonal of \( A \) is \( (A_{1,\sigma(1)}, \ldots, A_{n,\sigma(n)}) \) where \( \sigma \) is a permutation of \( [n] \), and the main diagonal is \( \text{diag}(A) = (A_{1,1}, \ldots, A_{n,n}) \). \( A \) has support if there exists a positive diagonal. \( A \) has total support if every non-zero entry of \( A \) belongs to a positive diagonal. \( A \) is irreducible if for every \( i, j \in [n] \), there exists an integer \( N \geq 1 \) such that \( A_{i,j}^N > 0 \). \( A \) is fully indecomposable if there exist no non-empty proper subsets \( X, Y \subseteq [n] \) such that \( \#X + \#Y = n \) and \( A_{i,j} = 0 \) for every \( i \in X \) and \( j \in Y \) (if the restriction is relaxed by requiring \( X \cap Y = \emptyset \), then a definition equivalent to being irreducible is obtained). Let

\[
\begin{align*}
M^r &= \{ A : A \text{ is a square } \mathbb{R}^+ \text{-matrix with no zero rows} \} \\
M^c &= \{ A : A \text{ is a square } \mathbb{R}^+ \text{-matrix with no zero columns} \} \\
M &= M^r \cap M^c \\
P^r &= \{ A \in M^r : A \text{ is row stochastic} \} \\
P^c &= \{ A \in M^c : A \text{ is column stochastic} \} \\
P &= P^r \cap P^c \\
B^r &= \{ A \in M^r : A \text{ satisfies the row condition} \} \text{ in Theorem 3.4} \\
B^c &= \{ A \in M^c : A \text{ satisfies the column condition} \} \text{ in Theorem 3.4} \\
B &= B^r \cap B^c \\
S &= \{ A \in M : A \text{ has support} \} \\
TS &= \{ A \in S : A \text{ has total support} \} \\
I &= \{ A \in M : A \text{ is irreducible} \} \\
FI &= \{ A \in I : A \text{ is fully indecomposable} \} \\
D &= \{ D \in M : D \text{ is a diagonal matrix with a positive diagonal} \}.
\end{align*}
\]

By a row (resp., column) stochastic form, we will mean a function \( f : X \to Y \), where \( X \subseteq M^r \) (resp., \( X \subseteq M^c \)) and \( Y \subseteq P^r \) (resp., \( Y \subseteq P^c \)). If \( Y \subseteq P \), then we say that \( f \) is a doubly stochastic form. Unless otherwise stated, we only consider stochastic forms \( f \) that are diagonal forms, i.e., \( f \) normalizes the matrix \( A \) by a rule

\[
A \overset{\Delta}{\rightarrow} \alpha D^{(r)}AD^{(c)} \quad \text{with} \quad \alpha > 0 \quad \text{and} \quad D^{(r)}, D^{(c)} \in D,
\]

and here \( D^{(r)}, D^{(c)} \) and \( \alpha \) depend on \( A \) (and so they are actually functions of \( A \)). To represent a diagonal form like this we will write

\[
f \leftarrow (\alpha; D^{(r)}, D^{(c)}).
\]

Diagonal forms are pattern-invariant, that is, the original matrix and its image have the same size and the same pattern, i.e. the positions of their non-zero entries coincide,
since for every \( i, j \in [n] \) we have
\[
A_{i,j} > 0 \iff f(A)_{i,j} = \alpha D_{i,i}^{(r)} A_{i,j} D_{j,j}^{(c)} > 0.
\]

Then \( A \) will have (total) support if and only if \( f(A) \) does, and the same holds for the properties of being irreducible and fully indecomposable. \( A \) has a doubly stochastic pattern if it has the pattern of a a doubly stochastic matrix. Also, \( A \) has a graph (or symmetric) pattern if it has the pattern of a symmetric matrix.

Recall the following two well known products of matrices: Let \( A \) and \( B \) be two real matrices of sizes \( h \times k \) and \( p \times q \) respectively. The Kronecker (or tensor) product of \( A \) and \( B \) is the matrix \( A \otimes B \) of size \( hp \times kq \) defined by
\[
A \otimes B = \begin{pmatrix}
A_{1,1}B & A_{1,2}B & \cdots & A_{1,k}B \\
A_{2,1}B & A_{2,2}B & \cdots & A_{2,k}B \\
\vdots & \vdots & \ddots & \vdots \\
A_{h,1}B & A_{h,2}B & \cdots & A_{h,k}B
\end{pmatrix}.
\]

If \( A \) and \( B \) have the same size (i.e., \( p = h \) and \( q = k \)), then the Hadamard product of \( A \) and \( B \) is the matrix \( C = A \odot B \) of size \( h \times k \) defined by
\[
C_{i,j} = A_{i,j} B_{i,j} \quad \text{for every } i \in [h] \text{ and } j \in [k].
\]

Let \( \frac{1}{A} \) be the matrix defined by the rule\(^1\)
\[
\left( \frac{1}{A} \right)_{i,j} = \begin{cases} 
\frac{1}{A_{i,j}} & \text{if } A_{i,j} \neq 0, \\
0 & \text{otherwise}
\end{cases}
\]

for every \( i \in [h] \) and \( j \in [k] \). We will also write \( A/B = A \odot B = A \odot \frac{1}{B} \).

3. Stochastic forms. Henceforth, unless otherwise stated, \( A \) and \( B \) are square matrices of size \( n \geq 1 \).

3.1. Standard. Let \( A \in M^r \) (resp., \( A \in M^c \)). Let \( S_A^{(r)} \in D \) (resp., \( S_A^{(c)} \in D \)) be the diagonal matrix with the positive diagonal \( \text{diag}(S_A^{(r)}) = \mathbf{r}_A = (r_1^{(A)}, \ldots, r_n^{(A)})^T = AJ_n \).

\(^1\)Observe that if \( A \) is invertible and its inverse is \( A^{-1} \), then, in general, \( A^{-1} \neq \frac{1}{A} \), but in the particular case when \( A \) is a diagonal matrix with no zero entries in the diagonal, then \( A^{-1} = \frac{1}{A} \).
The standard row (resp., column) stochastic form $S^r: M^r \to P^r$ (resp., $S^c: M^c \to P^c$) is defined by

$$S^r \leftarrow \left(1; \frac{1}{S^r_A} J_n\right) \quad \text{(resp., } S^c \leftarrow \left(1; \frac{1}{S^c_A} \right)),$$

**Proposition 3.1.** Let $A \in M^r$ (resp., $A \in M^c$). Suppose that $D \in \mathcal{D}$ is such that $D^{-1} A \in P^r$ (resp., $AD^{-1} \in P^c$), or in other words, that $A$ admits a stochastic form $(1; D^{-1}, I_n)$ (resp., $(1; I_n, D^{-1})$). Then $S^r \leftarrow (1; D^{-1}, I_n)$ (resp., $S^c \leftarrow (1; I_n, D^{-1})$), or more precisely, $D = S^r_A (\text{resp., } D = S^c_A)$.

**Proof.** It is straightforward.

**Proposition 3.2.** Let $A, B \in M^r$ (resp., $A, B \in M^c$). Then $S^r(A) = S^r(B)$ (resp., $S^c(A) = S^c(B)$) if and only if there exists a unique diagonal matrix $D \in \mathcal{D}$ such that $A = DB$ (resp., $A = BD$). The matrix $D$ is given by

$$\text{diag}(D) = \frac{r_A}{r_B}, \quad \text{(resp., } \text{diag}(D) = \frac{c_A}{c_B}).$$

**Proof.** $S^r(A) = S^r(B)$ (resp., $S^c(A) = S^c(B)$) if and only if the diagonal matrix $D \in \mathcal{D}$ defined by $\text{diag}(D)^T = \frac{r_A}{r_B}$ (resp., $\text{diag}(D) = \frac{c_A}{c_B}$) yields $A = DB$ (resp., $A = BD$). Uniqueness follows from Proposition [3.1].

The standard stochastic form is very common and occurs in a large number of works. There are surveys with references on the subject, starting with Lovasz’s [25], also [9], and books [15, 43]. Contributions vary among the many application models [1]. They include many aspects like limiting distributions [10], hitting times [3, 33], results under positive recurrence [30], entropy [41], graph reconstruction [42], cuts [11], networks [39, 40] and applications to genomic data [20].

### 3.2. Sinkhorn-Knopp

The Sinkhorn-Knopp doubly stochastic form $S: S \to P$ is defined for a matrix $A \in S$ by\footnote{Here $\circ$ denotes composition, not Hadamard product, henceforth it will be clear from context.}

$$S(A) := \lim_{k \to \infty} (S^c \circ S^r)^k(A). \quad (3.1)$$

In [37] Sinkhorn showed that if $A$ is a positive matrix, then $S(A)$ is well defined and converges to a doubly stochastic matrix. Moreover, he showed that, in the domain
of positive square matrices, $S$ is a diagonal form, i.e. there exist $D^{(r)}, D^{(c)} \in D$ (depending on $A$) so that $S \leftarrow (1; D^{(r)}, D^{(c)})$. He even proved that if $E^{(r)}, E^{(c)} \in D$ are such that $E^{(r)} A E^{(c)}$ is doubly stochastic, then there exists $p > 0$ such that $E^{(r)} = p D^{(r)}$ and $E^{(c)} = p^{-1} D^{(c)}$, i.e., $D^{(r)}$ and $D^{(c)}$ are unique up to a scalar factor (see Theorem 3.3 below). This setting was studied by other authors too: In [27], Marcus and Newman proved the existence of doubly stochastic diagonal forms for positive square matrices using the Brower fixed point theorem (Maxfield and Minc work on the problem too in [28]).

Sinkhorn and Knopp studied this more general case and the following is the main result in [38].

**Theorem 3.3 (Sinkhorn-Knopp [38]).** Let $A \in M$.

1. $A \in S$ if and only if $\lim_{k \to \infty} (S^c \circ S^r)^k(A)$ converges to an element in $P$.
2. $A \in TS$ if and only if there exist $B \in P$ and $D^{(r)}, D^{(c)} \in D$ such that $B = D^{(r)} A D^{(c)}$.
3. If $A \in TS$ and $B$, $D^{(r)}$ and $D^{(c)}$ are as in 2, then $B$ is unique, but it may be that $D^{(r)}$ and $D^{(c)}$ are not unique (up to a scalar factor).
4. If $A \in TS$, then $D^{(r)}$ and $D^{(c)}$ in 2 are unique (up to a scalar factor) if and only if $A \in FI$.
5. If $A \in TS$, then $\lim_{k \to \infty} (S^c \circ S^r)^k(A) = D^{(r)} A D^{(c)}$ for some $D^{(r)}, D^{(c)} \in D$.
6. If $A \in S \setminus TS$, then there are no $D^{(r)}, D^{(c)} \in D$ such that $\lim_{k \to \infty} (S^c \circ S^r)^k(A) = D^{(r)} A D^{(c)}$.

This more general situation in which the domain is further from positive matrices has also been studied by other authors: In [35], Perfect and Mirsky show that $A \in TS$ if and only if $A$ has a doubly stochastic pattern (compare with 2 in Theorem 3.3). London [21] as well as Letac [22] showed that $A$ has a doubly stochastic pattern if and only if there exists $B$ and $D^{(r)}, D^{(c)} \in D$ as in 2 in Theorem 3.3. Based on the nonlinear operator introduced by Menon in [29], Brualdi, Parter and Schneider proved in [8] parts of Theorem 3.3, namely 2 and one direction of 4 (the assumption: full indecomposability).

### 3.3. Brualdi-Parter-Schneider.

In [8], stochastic forms $(1; D, D)$ with $D \in D$ are introduced and studied. We refer to such stochastic forms as Brualdi-Parter-...
Stochastic Forms of Non-Negative Matrices and Perron-Regularity

Schneider.

**Theorem 3.4** (Brualdi, Parter and Schneider [8]). Let \( A \in M^n \) (resp., \( A \in M^c \)). Then for any non-negative matrix \( B \) with the same pattern as \( A \), there exists \( D \in D \) such that \( DBD \in P^n \) (resp., \( DBD \in P^c \)) if and only if the following condition is satisfied:

1. If the rows and columns of \( A \) are permuted simultaneously so that \( A_{i,j} = 0 \) for \( 1 \leq i, j \leq s \), then there exists \( k \) and \( l \) with \( s < k \leq n \) and \( 1 \leq l \leq s \) such that \( A_{k,j} = 0 \) (resp., \( A_{j,k} = 0 \)) for \( j = 1, \ldots, s \) and \( A_{l,k} > 0 \) (resp., \( A_{k,l} > 0 \)).

In this case, the matrix \( D \) is unique.

**Corollary 3.5** (Brualdi, Parter and Schneider [8]). If \( A \in M \) has a positive main diagonal, then condition 1 in Theorem 3.4 holds.

**Corollary 3.6** (Brualdi, Parter and Schneider [8]). If \( A \in M \) is symmetric, then condition 1 in Theorem 3.4 holds if and only if the main diagonal of \( A \) is positive.

We let \( B^r: B^r \to P^n \) (resp., \( B^c: B^c \to P^c \)) denote the Brualdi-Parter-Schneider row (resp., column) stochastic form. For \( A \in B^r \) (resp., \( A \in B^c \)), let \( D^{(r)}_A \) (resp., \( D^{(c)}_A \)) be the unique matrix in \( D \) such that \( B^r(A) = D^{(r)}_A AD^{(r)}_A \) (resp., \( B^c(A) = D^{(c)}_A AD^{(c)}_A \)).

**Remark 3.7.** If \( A \in B \), then \( \lim_{k \to \infty} (B^c \circ B^r)^k(A) \) converges to a doubly stochastic matrix and there exists \( D \in D \) such that \( D^{(c)}_A AD^{(c)}_A \). By the uniqueness property in Theorem 3.4

\[ B^r(A) = \lim_{k \to \infty} (B^c \circ B^r)^k(A) = B^c(A). \]

(See Theorem 4.13).

**Proposition 3.8.** Let \( A, B \in B^r \) (resp., \( A, B \in B^c \)). Then \( B^r(A) = B^r(B) \) (resp., \( B^c(A) = B^c(B) \)) if and only if there exists a unique diagonal matrix \( D \in D \) such that \( A = DBD \). In this case, \( D \) is given by

\[
\text{diag}(D) = \frac{\text{diag} \left( D^{(c)}_B \right)}{\text{diag} \left( D^{(r)}_B \right)} \quad \text{(resp., } \frac{\text{diag} \left( D^{(c)}_B \right)}{\text{diag} \left( D^{(r)}_A \right)} \text{).}
\]

Proof. \( B^r(A) = B^r(B) \) if and only if \( A = \left( D^{(r)}_A \right)^{-1} D^{(c)}_B BD^{(r)}_B \left( D^{(r)}_A \right)^{-1} \). Then the result follows from the fact that \( DE = ED \) for every \( D, E \in D \) and from the uniqueness property in Theorem 3.4.

The rest of the proof is analogous. \( \Box \)
3.4. Perron. The Perron stochastic form is defined for an irreducible matrix \( A \in I \). Let \( \lambda_A > 0 \) be the Perron value of \( A \) and let \( p_A = (p_A^{(1)}, \ldots, p_A^{(q)})^T \) and \( q_A = (q_A^{(1)}, \ldots, q_A^{(q)}) \) be right and left Perron eigenvectors of \( A \) respectively (that is, \( \lambda_A > 0 \) is the spectral radius of \( A \), \( A p_A = \lambda_A p_A \), \( q_A A = \lambda_A q_A \) and both \( p_A \) and \( q_A \) are positive). Let \( P_A, Q_A \in D \) be defined by \( \text{diag}(P_A) = p_A^T \) and \( \text{diag}(Q_A) = q_A \). The Perron row (resp., column) stochastic form \( P^r : I \to P^r \) (resp., \( P^c : I \to P^c \)) is defined by

\[
P^r \leftarrow \left( \frac{1}{\lambda_A} ; \frac{1}{P_A} ; P_A \right) \quad \text{(resp.,} \quad P^c \leftarrow \left( \frac{1}{\lambda_A} ; Q_A ; \frac{1}{Q_A} \right) \right). \tag{3.2}
\]

Proposition 3.9 \((26)\). Let \( A \in I \). Let \( D \in D \) and \( \alpha > 0 \), and define \( B = \alpha D^{-1} A D \) (resp., \( B = \alpha D A D^{-1} \)). If \( B \in P^r \) (resp., \( B \in P^c \)), then \( B = P^r(A) \) (resp., \( B = P^c(A) \)), \( \alpha = \lambda_A^{-1} \) and \( D \) is equal to \( P_A \) (resp., \( Q_A \)) modulo a positive scalar multiple.

We include a proof for completeness.

Proof. Let \( d = \text{diag}(D)^T \) and suppose that \( \alpha D^{-1} A D \in P^r \) (resp., \( \alpha D A D^{-1} \in P^c \)). Then \( A d = \frac{1}{\alpha} d \) (resp., \( d^T A = \frac{1}{\alpha} d^T \)), and then the Perron-Frobenius Theorem implies the result. \( \square \)

Corollary 3.10. If \( A \in P^r \cap I \), then \( P^r \circ P^c(A) = A \) and \( P^c \circ P^r(A^T) = A^T \).

Proof. Since \( P^r \circ P^c(A) = (Q_A^{-1} P^r(A))^{-1} A (Q_A^{-1} P^c(A)) \) is stochastic, Proposition 3.9 implies that \( Q_A^{-1} P^c(A) \) is a scalar multiple of the identity matrix \( I_n \) (since \( P^r(A) = A = I_n^{-1} A I_n \)). Then

\[
\frac{p_i^{(P^c(A))}}{p_j^{(P^c(A))}} = \frac{q_i(A)}{q_j(A)} \quad \text{for every } i, j \in [n]
\]

and the first claim follows. The second one is analogous. \( \square \)

Remark 3.11. Corollary 3.10 implies that if \( A \in I \), then

\[
\lim_{k \to \infty} (P^c \circ P^r)^k(A)
\]

converges if and only if \( P^r(A) \in P \), and in this case it converges to \( P^r(A) \). (See Theorem 3.13)

Proposition 3.12 \((26)\). Let \( A, B \in I \). Then \( P^r(A) = P^r(B) \) (resp., \( P^c(A) = P^c(B) \)) if and only if there exists \( D \in D \) and a real number \( \rho > 0 \) such that

\[
A = \frac{D^{-1} B D}{\rho} \quad \text{(resp.,} \quad A = \frac{D B D^{-1}}{\rho}) \tag{3.3}\]

The matrix $D$ is, up to a scalar multiple, given by
\[ \text{diag}(D) = \frac{p_B}{p_A} \quad \text{(resp., } \text{diag}(D) = \frac{q_B}{q_A} \text{)} . \]

Compare with Propositions 3.2 and 3.8. We include a proof for completeness.

**Proof.** Suppose that $\mathcal{P}_r(A) = \mathcal{P}_r(B)$ (resp., $\mathcal{P}_c(A) = \mathcal{P}_c(B)$). If $D \in \mathcal{D}$ is defined by $\text{diag}(D)^T = \frac{p_B}{p_A}$ (resp., $\text{diag}(D) = \frac{q_B}{q_A}$) and $\rho = \frac{\lambda_B}{\lambda_A}$, then it is straightforward to check that (3.3) holds.

Conversely, suppose that (3.3) holds. Then
\[ \mathcal{P}_r(A) = \frac{(DP_A)^{-1}B(DP_A)}{\rho \lambda_A} \quad \text{(resp., } \mathcal{P}_c(A) = \frac{(DQ_A)B(DQ_A)^{-1}}{\rho \lambda_A} \text{)} . \]
is stochastic. Therefore, $\lambda_B = \rho \lambda_A$ and $p_B = (DP_A I_n)^T$ (resp., $q_B = I_n DQ_A$) (by uniqueness, up to a positive scale factor, of Perron vectors). Then $\mathcal{P}_r(B) = \mathcal{P}_r(A)$ (resp., $\mathcal{P}_c(B) = \mathcal{P}_c(A)$).

The Perron stochastic form appears in the proof of the Perron-Frobenius Theorem (see e.g. [6, 12, 36], or also [16] for a historical approach in relationship with continued fractions). It has been used in symbolic dynamics (the books [21, 23] are classic introductions to this subject): With it Marcus and Tuncel [26] study classification problems of Markov chains presented by matrices over positive integral semirings of exponential functions. Parry discovered that the Perron stochastic form restricted to irreducible $\{0, 1\}$-matrices induces the unique probability measures of maximal entropy on the (vertex) shift spaces associated to these type of matrices (see [34] for details).

4. **Intersections.** In this section, we address the problem of determining when two stochastic forms of a given matrix coincide. Observe that determining when a row stochastic form coincides with a column stochastic form corresponds to considering when either stochastic form coincides with the Sinkhorn-Knopp doubly stochastic form.

4.1. **Standard and Sinkhorn-Knopp.** In this first case, we look at matrices $A \in \mathbf{M}$ such that $\mathcal{S}_r(A)$ (and $\mathcal{S}_c(A)$) are doubly stochastic.

**Proposition 4.1.** Let $A \in \mathbf{M}$. If $\mathcal{S}_r(A) \in \mathbf{P}$ (resp., $\mathcal{S}_c(A) \in \mathbf{P}$), then $A \in \mathbf{TS}$ and $\mathcal{S}_r(A) = \mathcal{S}(A) = \mathcal{S}_c(A)$. Moreover, if $A \in \mathbf{FI}$, then $\mathcal{S}_r(A) \in \mathbf{P}$ (resp., $\mathcal{S}_c(A) \in \mathbf{P}$) if and only if $\mathcal{S}_r(A) = \mathcal{S}_c(A)$. 
Proof. Suppose that $\mathcal{S}^r(A) = \left( S_{A}^{(r)} \right)^{-1} A = \left( S_{A}^{(c)} \right)^{-1} A_{i,j} \in P$. Then $2$ in Theorem 3.3 implies that $A \in TS$. It follows from $5$ and $3$ in Theorem 3.3 that $\mathcal{S}^r(A) = S(A)$. If, in addition, $A \in FI$, then $4$ in Theorem 3.3 implies that there exists a constant $\kappa > 0$ such that $S_{A}^{(r)} = \kappa S_{A}^{(c)}$, but then $r_{A} \cdot J_{n}^{T} = \kappa c_{A} \cdot J_{n}$, and hence, $\kappa = 1$. Clearly, if $\mathcal{S}^r(A) = S^c(A)$, then $\mathcal{S}^r(A) \in P$.

The rest of the proof is analogous. □

The following is a particular instance of Proposition 4.1.

**Proposition 4.2.** Let $A \in M$. Then $\mathcal{S}^r(A) = S(A) = S^c(A)$ if and only if $r_{i}^{(A)} = c_{j}^{(A)}$ for every $i, j \in [n]$ such that $A_{i,j} \neq 0$.

Proof. $\mathcal{S}^r(A) = S^c(A)$ if and only if $\left( S_{A}^{(r)} \right)^{-1} A = A \left( S_{A}^{(c)} \right)^{-1}$ and this holds if and only if

$$\frac{r_{i}^{(A)}}{c_{j}^{(A)}} A_{i,j} = A_{i,j} \quad \text{for every } i, j \in [n]. \quad \Box$$

The condition in Proposition 4.2 can be compared with that of reversible systems (see e.g. [2, 14, 15]), i.e., with symmetric doubly stochastic matrices, in particular if the matrix has positive entries.

**Example 4.3.** The matrix $A = \begin{pmatrix} 0 & 1 & 2 \\ 0 & 10 & 5 \\ 1 & 0 & 0 \end{pmatrix}$ has total support but is not fully indecomposable, $\mathcal{S}^r(A) = \begin{pmatrix} 0 & 1 & 2 \\ 0 & \frac{1}{3} & \frac{2}{3} \\ 1 & 0 & 0 \end{pmatrix} \in P$ but $\mathcal{S}^r(A) \neq S^c(A)$ (e.g. $A_{1,2} \neq 0$ and $r_{1}^{(A)} = 3 \neq 11 = c_{2}^{(A)}$), and two distinct representations (not equal modulo a positive scalar multiple) of $\mathcal{S}^r(A)$ as a diagonal form are

$$\begin{pmatrix} \frac{1}{3} & 0 & 0 \\ 0 & \frac{1}{5} & 0 \\ 0 & 0 & 1 \end{pmatrix} A \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 5 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} A \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{5} & 0 \\ 0 & 0 & \frac{1}{15} \end{pmatrix},$$

the last being the form of the limit process of iterating $S^c \circ S^r$ on $A$.

**Proposition 4.4.** Let $A, B \in M$ and suppose that $\mathcal{S}^r(A) = S(A) = S^c(A)$ and $\mathcal{S}^r(B) = S(B) = S^c(B)$. Then $\mathcal{S}^r(A \otimes B) = S(A \otimes B) = S^c(A \otimes B)$.

Proof. Let the sizes of $A$ and $B$ be $n \geq 1$ and $m \geq 1$ respectively. If $i, j \in [n]$ and
4.3. Standard and Perron. In this case, we are considering sums of rows (and columns) of matrices together with (Perron) eigenpairs. Similar contexts have been previously considered, e.g. to study sums of columns of row stochastic matrices together with their spectra as well as their stationary distributions [18, 19].

To start, we first define “locally constant” vectors and “Perron-regularity”. For each \( i \in [n] \), let the row (resp., column) neighborhood of \( i \) be

\[
N_i^A = \{ j \in [n] : A_{i,j} \neq 0 \} \quad \text{ (resp., } N_i^A = \{ j \in [n] : A_{j,i} \neq 0 \}).
\]
Fig. 4.1. Three different examples of directed graphs on four vertices and the form of their corresponding locally row constant vectors. (i) Any vector is locally row constant. (ii) A locally row constant vector must have the first two entries equal. (iii) A locally row constant vector must have the first three entries equal.

A column (resp., row) $n$-vector $v = (v_1, \ldots, v_n)^T$ (resp., $v = (v_1, \ldots, v_n)$) is locally row (resp., column) constant with respect to $A$ if for each $i \in [n]$ we have $v_j = v_k$ for every $j, k \in N_A^r(i)$ (resp., $N_A^c(i)$). In this case, let

$$v^r = \left( v_1^{(r)}, \ldots, v_n^{(r)} \right)^T \quad \text{resp.,} \quad v^c = \left( v_1^{(c)}, \ldots, v_n^{(c)} \right),$$

where $v_j^{(r)} = v_j$ (resp., $v_j^{(c)} = v_j$) for some (every) $j \in N_A^r(i)$ (resp., $j \in N_A^c(i)$). If a vector is locally row (resp., column) constant with respect to a matrix $A$, then it is locally row (resp., column) constant with respect to any matrix $B$ with the same pattern as $A$. Henceforth we will simply refer to a vector as locally (row or column) constant as long as it is clear in the context with respect to which matrix pattern.

Figure 4.1 illustrates with directed graphs examples of locally row constant vectors (see Section 5 for more on directed graphs associated to matrices).

**Definition 4.7.** A $A \in \mathbf{I}$ is row (resp., column) Perron-regular if its right (resp., left) Perron vector $p_A$ (resp., $q_A$) is locally row (resp., column) constant (with respect to $A$ itself).

**Theorem 4.8.** An irreducible matrix $A \in \mathbf{I}$ is row (resp., column) Perron-regular if and only if $S^r(A) = P^r(A)$ (resp., $S^c(A) = P^c(A)$).

**Proof.** If $S^r(A) = P^r(A)$, then

$$\frac{A_{i,j}}{r_i^{(A)}} = \frac{p_{i}^{(A)}}{\lambda_A p_{i}^{(A)}} A_{i,j} \quad \text{for every} \ i, j \in [n]. \quad (4.1)$$

Then for every $j \in N_A^r(i)$ we have $p_{j}^{(A)} = \frac{\lambda_A p_{i}^{(A)}}{r_i^{(A)}}$, so that the value of $p_{j}^{(A)}$ only depends on $i$. Then $p_A$ is locally row constant and hence $A$ is row Perron-regular.
Conversely, suppose that \( A \) is row Perron-regular. If \( i \in [n] \) and \( j \in N^r_A(i) \), then
\[
\lambda_A p_i^{(A)} - r_i^{(A)} p_j^{(A)} = \sum_{k=1}^n A_{i,k} \left( p_k^{(A)} - p_j^{(A)} \right) = \sum_{k \in N^r_A(i)} A_{i,k} \left( p_k^{(A)} - p_j^{(A)} \right) = 0
\]
because \( p_A \) is locally row constant. Therefore, (4.11) holds, and hence, \( S^r(A) = P^r(A) \).

The rest of the proof is analogous. \( \square \)

**Proposition 4.9.** If \( A \in \mathbf{I} \) is row (resp., column) Perron-regular, then
\[
\lambda_A p_A = r_A \circ p_A' \quad (\text{resp., } \lambda_A q_A = c_A \circ q_A')
\]

**Proof.** If \( A \) is row Perron-regular, then
\[
\lambda_A p_i^{(A)} = \sum_{j \in N^r_A(i)} A_{i,j} p_j^{(A)} = \left( p_i^{(A)} \right)^{(r)} \sum_{j \in N^r_A(i)} A_{i,j} = \left( p_i^{(A)} \right)^{(r)} c_i^{(A)}
\]
for every \( i \in [n] \).

The rest of the proof is analogous. \( \square \)

**Remark 4.10.** Proposition 4.12 characterizes when two irreducible matrices \( A \) and \( B \) yield the same Perron stochastic form. This can occur even if \( A \) is Perron-regular whereas \( B \) is not since for any \( D \in \mathbf{D} \) and \( \rho > 0 \), if \( B = D^{-1} A D \)
\[
\left( \text{resp., } B = D^{-1} A D \right)
\]
then \( \lambda_B = \frac{\lambda_A}{\rho} \) and \( p_B = \frac{p_A}{\text{diag}(D)} \left( \text{resp., } q_B = \frac{q_A}{\text{diag}(D)} \right) \).

**Corollary 4.11.** Let \( A, B \in \mathbf{I} \) be such that \( P^r(A) = P^r(B) \) (resp., \( P^c(A) = P^c(B) \)). If \( \frac{p_A}{p_B} \left( \text{resp., } \frac{q_A}{q_B} \right) \) is locally row (resp., column) constant, then \( A \) is row (resp., column) Perron-regular if and only if \( B \) is row (resp., column) Perron-regular.

**Proof.** It follows from Remark 4.10. \( \square \)

**Theorem 4.12.** Let \( A, B \in \mathbf{I} \) be row (resp., column) Perron-regular matrices. Then \( A \otimes B \) is row (resp., column) Perron-regular.

**Proof.** Clearly, \( A \otimes B \in \mathbf{I} \). Suppose that the sizes of \( A \) and \( B \) are \( n \geq 1 \) and \( m \geq 1 \) respectively. We only prove the case for rows since the case for columns is analogous.

Let \( \{\lambda_i, v^{(i)}\}_{i \in [n]} \) and \( \{\mu_j, w^{(j)}\}_{j \in [m]} \) be the right eigenpairs of \( A \) and \( B \) respectively. Then \( \{(\lambda_i \mu_j, v^{(i)} \otimes w^{(j)})\}_{i \in [n], j \in [m]} \) are the right eigenpairs of \( A \otimes B \). In
particular, if \((\lambda, \mathbf{v})\) and \((\mu, \mathbf{w})\) are the right Perron eigenpairs of \(A\) and \(B\) respectively, then the Perron-Frobenius Theorem implies that \((\lambda \mu, \mathbf{v} \otimes \mathbf{w})\) is the right Perron eigenpair of \(A \otimes B\). Given \(k \in [nm]\), let \(i, j \in [nm]\) be such that \((A \otimes B)_{k,i}, (A \otimes B)_{k,j} > 0\).

Let \(a, b, c \in \{0, \ldots, n-1\}\) and \(r, s, t \in [m]\) be such that \(k = an + r, i = bn + s\) and \(j = cn + t\). Since

\[(A \otimes B)_{k,i} = A_{a+1,b+1}B_{r,s} > 0 \quad \text{and} \quad (A \otimes B)_{k,j} = A_{a+1,c+1}B_{r,t} > 0,
\]

the row Perron-regularity of \(A\) and \(B\) imply that \(v_{b+1} = v_{c+1}\) and \(w_s = w_t\), hence

\[(\mathbf{v} \otimes \mathbf{w})_{k,i} = v_{b+1}w_s = v_{c+1}w_t = (\mathbf{v} \otimes \mathbf{w})_{k,j}.
\]

Therefore, the result follows from Theorem 4.8.

4.4. Sinkhorn-Knopp and Brualdi-Parter-Schneider. Here we look at the case when the Brualdi-Parter-Schneider normalization is doubly stochastic.

**Theorem 4.13.** Let \(A \in B^r\) (resp., \(A \in B^c\)). Then \(B^r(A) \in P\) (resp., \(B^c(A) \in P\)) if and only if there exists a (unique) positive solution \(\mathbf{x} = (x_1, \ldots, x_n)\) to the homogeneous linear system

\[\mathbf{x}(A - A^T) = 0 \quad (4.2)
\]

(in particular \(\det(A - A^T) = 0\)) which satisfies

\[x_j \sum_{i=1}^{n} x_i A_{i,j} = x_j \sum_{i=1}^{n} x_i A_{j,i} = 1 \quad \text{for every} \quad j \in [n]. \quad (4.3)
\]

*In this case, \(A \in TS\) and \(B^r(A) = B^c(A) = S(A)\).*

**Proof.** Let \(D = D_A^{(r)}\). Then \(B^r(D) \in P\) if and only if

\[\sum_{i=1}^{n} D_{i,i} D_{j,j} A_{i,j} = 1 \quad \text{and} \quad \sum_{i=1}^{n} D_{i,i} D_{j,j} A_{j,i} = 1
\]

for every \(j \in [n]\), in particular

\[\sum_{i=1}^{n} D_{i,i} (A_{i,j} - A_{j,i}) = 0 \quad \text{for every} \quad j \in [n],
\]

i.e., \(\mathbf{x} = \text{diag}(D)\) is a positive solution to \((4.2)\) which satisfies \((4.3)\) for every \(j \in [n]\) (with \(a = 1\)). Conversely, if \(\mathbf{x}\) is a positive solution to \((4.2)\) satisfying \((4.3)\), then it follows that \(D \in D\) defined by \(\text{diag}(D) = \mathbf{x}\) is such that \(DAD \in P\), and the unicity property in Theorem 3.4 implies that \(B^r(A) = DAD\), and therefore, also \(B^c(A) = B^c(A)\)
If \( B^r(D) \in \mathbf{P} \), then 2 in Theorem 3.3 implies that \( A \in \mathbf{TS} \), and hence 5 and 3 in Theorem 3.3 imply that \( B^r(A) = S(A) \).

**Theorem 4.14.** Let \( A, B \in \mathbf{B} \) and suppose that \( B^r(A) = S(A) = B^c(A) \) and \( B^r(B) = S(B) = B^c(B) \). Then \( B^r(A \otimes B) = S(A \otimes B) = B^c(A \otimes B) \).

**Proof.** Let the sizes of \( A \) and \( B \) be \( n \geq 1 \) and \( m \geq 1 \) respectively. Let \( \mathbf{x} = (x_1, \ldots, x_n) \) and \( \mathbf{y} = (y_1, \ldots, y_m) \) be the solutions to (4.2) that satisfy (4.3) for \( A \) and \( B \) respectively. For every \( i \in [n] \) and \( j \in [m] \) we have

\[
((\mathbf{x} \otimes \mathbf{y}(A \otimes B - (A \otimes B)^T))_{(i-1)m+j} = \sum_{h=1}^{n} \sum_{k=1}^{m} x_h y_k (A_{h,i} B_{k,j} - A_{i,h} B_{j,k})
\]

\[
= \sum_{h=1}^{n} x_h A_{h,i} \sum_{k=1}^{m} y_k B_{k,j} - \sum_{h=1}^{n} x_h A_{i,h} \sum_{k=1}^{m} y_k B_{j,k}
\]

\[
= \left( \sum_{h=1}^{n} (x_h A_{h,i} - x_h A_{i,h}) \right) \left( \sum_{k=1}^{m} (y_k B_{k,j} - y_k B_{j,k}) \right) = 0.
\]

(the third and last equalities hold by hypothesis). Then \( \mathbf{x} \otimes \mathbf{y} \) is a solution to (4.2). To finish,

\[
x_i y_j \sum_{h=1}^{n} \sum_{k=1}^{m} x_h y_k A_{h,i} B_{k,j} = x_i \sum_{h=1}^{n} x_h A_{h,i} \left( y_j \sum_{k=1}^{m} y_k B_{k,j} \right) = 1.
\]

(the last equality holds by hypothesis). Then \( \mathbf{x} \otimes \mathbf{y} \) satisfies (4.3) for \( A \otimes B \). The result now follows from Theorem 4.13. \( \square \)

**4.5. Sinkhorn-Knopp and Perron.** Here we look at the case when the Perron stochastic form is doubly stochastic.

**Theorem 4.15.** Let \( A \in \mathbf{I} \). The following are equivalent:

1. \( \mathcal{P}^r(A) \in \mathbf{P} \).
2. \( \mathcal{P}^c(A) \in \mathbf{P} \).
3. \( \mathcal{P}^r(A) = \mathcal{P}^c(A) \).
4. \( (\mathbf{P}^{-1}_A)^T \) is a left eigenvector of \( A \).
5. \( (\mathbf{Q}^{-1}_A)^T \) is a right eigenvector of \( A \).
6. \( \mathcal{P}^r(A) = S(A) \).
7. \( \mathcal{P}^c(A) = S(A) \).

**Proof.** \( \mathcal{P}^r(A) \in \mathbf{P} \) if and only if

\[
J_n^T \frac{P_A^{-1} A P_A}{\lambda_A} = J_n^T,
\]
and this holds if and only if \((p_A^{-1})^T A = \lambda_A (p_A^{-1})^T\). Then \(\iff A \iff B\). Similarly, \(B \iff C\).

Clearly \(\iff A \iff B\). On the other hand, \(\iff A \iff B\) since the Perron-Frobenius Theorem implies that

\[
\mathcal{P}^e(A) = \frac{P_A^{-1} A p_A}{\lambda_A} = \mathcal{P}^e(A).
\]

Similarly, \(\iff B\).

Clearly \(\iff A \iff B\) and \(\iff A \iff B\). Conversely, if \(\mathcal{P}(A) \in P\), then \(A \equiv B\) in Theorem \(A\) implies that \(A \equiv B\) in particular \(\iff C\) and similarly \(\iff A \iff B\).

**Theorem 4.16.** Let \(A, B \in \mathcal{I}\) and suppose that \(\mathcal{P}^e(A) = S(A) = \mathcal{P}^e(B)\) and \(\mathcal{P}^e(A) = S(B) = \mathcal{P}^e(B)\). Then \(\mathcal{P}^e(A \otimes B) = S(A \otimes B) = \mathcal{P}^e(A \otimes B)\).

**Proof.** We already know that \(p_{A \otimes B} = p_A \otimes p_B\) (from the proof of Theorem \(4.12\)), hence \((p_{A \otimes B})^T = (p_A^{-1})^T \otimes (p_B^{-1})^T\) is a left eigenvector of \(A \otimes B\) (again from the proof of Theorem \(4.12\)). The result now follows from Theorem \(4.15\). 

**4.6. Brualdi-Parter-Schneider and Perron.** Here we look at the case when the Brualdi-Parter-Schneider and the Perron normalizations coincide.

**Proposition 4.17.** Let \(A \in \mathcal{I} \cap \mathcal{B}^r\) (resp., \(A \in \mathcal{I} \cap \mathcal{B}^c\)). Let \(D = D_A^{(e)}\) (resp., \(D = D_A^{(c)}\)) and let \(x = (x_1, \ldots, x_n)\) be \(x = p_A\) (resp., \(x = q_A\)). Then \(\mathcal{B}^r(A) = \mathcal{P}^r(A)\) (resp., \(\mathcal{B}^c(A) = \mathcal{P}^c(A)\)) if and only if

\[
\lambda_A D_i, i, j = x_j / x_i \quad \text{for every } i, j \in [n] \text{ such that } A_{i,j} \neq 0. \tag{4A}
\]

If this is the case and, in addition, \(A\) has a positive diagonal (in particular, if \(A\) is symmetric, see Corollary \(3.7\)), then \(A\) is a positive scalar multiple of a doubly stochastic matrix.

**Proof.** Clearly \(\mathcal{B}^r(A) = \mathcal{P}^r(A)\) (resp., \(\mathcal{B}^c(A) = \mathcal{P}^c(A)\)) if and only if \(\iff A\) holds. If in addition \(A\) has a positive diagonal, then \(D_{i,j} = \frac{1}{\sqrt{A_{i,j}}}\) for every \(i, j \in [n]\), in particular \(x_i = x_j\) for every \(i, j \in [n]\) such that \(A_{i,j} \neq 0\), but then irreducibility implies that \(x_i = x_j\) for every \(i, j \in [n]\) if and only if \(\iff A\) holds.

**Proposition 4.18.** Let \(A, B \in \mathcal{I} \cap \mathcal{B}^r\) (resp., \(A, B \in \mathcal{I} \cap \mathcal{B}^c\)) and suppose that

\[
\mathcal{B}^r(A) = \mathcal{P}^r(A) \quad \text{and} \quad \mathcal{B}^c(B) = \mathcal{P}^c(B).
\]

Then \(\mathcal{B}^r(A \otimes B) = \mathcal{P}^r(A \otimes B)\) (resp., \(\mathcal{B}^c(A \otimes B) = \mathcal{P}^c(A \otimes B)\)).
Stochastic Forms of Non-Negative Matrices and Perron-Regularity

Proof. Let the sizes of $A$ and $B$ be $n \geq 1$ and $m \geq 1$ respectively. Let $D = D_A^{(r)}$, $E = D_B^{(s)}$, $F = D_{A\otimes B}^{(s)}$, $x = p_A$, $y = p_B$ and $z = p_{A\otimes B} = p_A \otimes p_B$. It is easy to show that $F = D \otimes E$. For every $i,j \in [n]$ and $h,k \in [m]$ for which $(A \otimes B)_{m(i-1)+h,m(j-1)+k} = A_{i,j} B_{h,k} \neq 0$, we have

$$
\lambda_{A\otimes B} F_{m(i-1)+h,m(j-1)+k} F_{m(j-1)+k,m(i-1)+h} = \lambda_A \lambda_B D_{i,j} E_{h,k} D_{j,h} E_{k,h},
$$

Then (4.4) holds for $A \otimes B$, and hence, Proposition 4.17 implies the result for rows.

The rest of the proof is analogous. □

5. Directed graphs and Perron-regularity. We need to give more definitions and notation. For a complete reference to graphs and matrices see [5].

5.1. Graphs and matrices. Given a square $\mathbb{R}^+$-matrix $A$, let $A^\#$ be the zero-nonzero pattern of the matrix $A$, i.e., the $\{0,1\}$-matrix defined by

$$
A^\#_{i,j} = A^0_{i,j} \quad \text{for every } i,j \in [n], \text{ with } 0^0 = 0
$$

(then two matrices $A$ and $B$ have the same pattern if and only if $A^\# = B^\#$). Let $G = G(A^\#)$ be the (simple) directed graph with adjacency matrix $A^\#$, that is, $G$ consists of the vertex set $V = V(G) = [n]$ and edge set $E = E(G) = \{(i,j) \in V(G) \times V(G) : A^\#_{i,j} = 1\}$. There is also the corresponding weight function $\omega = \omega_A : E \to \mathbb{R}^+ \setminus \{0\}$ defined for every $(i,j) \in E$ by $\omega(i,j) = A_{i,j}$. $(G,\omega)$ is the weighted directed graph associate with $A$. $A$ and $(G,\omega)$ determine each other; in particular, $A^\#$ and $G$ do too. Henceforth all definitions about $A$ are translated to $(G,\omega)$ (or simply to $G$ if the definition depends solely on the pattern $A^\#$). For instance:

- A graph is a directed graph with symmetric adjacency matrix.
- A weighted directed graph $(G,\omega)$ is row (resp., column) Perron-regular if its associated $\mathbb{R}^+$-matrix $A = A(G,\omega)$ is row (resp., column) Perron-regular. In particular, a directed graph $G$ is row (resp., column) Perron-regular if its adjacency matrix $A^\# = A^\#(G)$ is row (resp., column) Perron-regular.
- Etc.

(We can also extend the notation given so far for matrices to directed graphs so that we can consistently exchange symbols, e.g. $N^+_v(G)$ will denote the row neighborhood of $v \in V$. Also, the forthcoming definitions and notation for weighted directed graphs are henceforth translated to matrices.) The weighted row (resp., column) degree of $v \in V$ is

$$
\delta^+_\omega(v) = r^\omega_v(A) \quad \text{(resp., } \delta^-_\omega(v) = c^\omega_v(A)\text{)}.
$$
and the (unweighted) row (resp., column) degree of \(v\) is
\[\delta^r_G(v) = r^v(A^\#) = |N^r_G(v)| \quad \text{(resp., } \delta^c_G(v) = c^v(A^\#) = |N^c_G(v)|).\]

\((G, \omega)\) is weight row (resp., column) regular if for some real number \(\alpha > 0\) we have
\[\delta^r_G(v) = \alpha \quad \text{(resp., } \delta^c_G(v) = \alpha) \quad \text{for every } v \in V.\]

In particular, \(G\) is row (resp., column) weight biregular if for some integer \(d > 0\) we have
\[\delta^r_G(v) = d \quad \text{(resp., } \delta^c_G(v) = d) \quad \text{for every } v \in V.\]

\(G\) is bipartite if there exists a partition of the vertex set such that if \((u, v) \in E\), then \(u\) and \(v\) belong to distinct parts, i.e., \(V = V_1 \cup V_2\), \(V_1 \cap V_2 = \emptyset\) and if \((u, v) \in E\), then \(u \in V_1\) and \(v \in V_2\) or \(u \in V_2\) and \(v \in V_1\). If \(G\) is bipartite, then \((G, \omega)\) is row (resp., column) weight biregular if \(\delta^r_G(v) = \delta^r_G(u)\) (resp., \(\delta^c_G(v) = \delta^c_G(u)\)) for every \(v, u \in V_i, i = 1, 2\). In particular, a directed graph \(G\) is row (resp., column) biregular if it is weight row (column) biregular for \(\omega: E \to \{1\}\), i.e., if \(\delta^r_G(v) = \delta^r_G(u)\) (resp., \(\delta^c_G(v) = \delta^c_G(u)\)) for every \(v, u \in V_i, i = 1, 2\).

A path in \(G\) of length \(\ell \geq 1\) is a sequence of vertices \(\gamma = (x_0, x_1, \ldots, x_\ell) \in V^{\ell+1}\) such that \((x_{i-1}, x_i) \in E\) for every \(i = 1, \ldots, \ell\). In this case, we say that \(\gamma\) is a \(x_0x_\ell\)-path. In terms of paths, \(G\) is strongly connected if for every pair of vertices \(u, v \in V\), there exists a \(uv\)-path in \(G\) (equivalently, \(A^\#(G)\) is irreducible). The path \(\gamma\) is:

- closed if \(x_0 = x_\ell\),
- a loop if it is closed and \(\ell = 1\) and
- reversible if \(\gamma^{-1} = (x_\ell, \ldots, x_1, x_0)\) is also a path in \(G\).

We say that \(G\) is connected by reversible paths if for every \(u, v \in V\), there exists a reversible \(uv\)-path. Clearly, directed graphs which are connected by reversible paths are strongly connected.

If \(G\) is actually a graph, then \(\delta^c_G(v) = \delta^c_G(v)\) for every \(v \in V\), and hence, we can define \(\delta_G(v)\) the degree of \(v\) as its row (or column) degree. Also, the graph \(G\) is regular if it is row (equivalently column) regular. \(G\) is a bipartite biregular graph if as a directed graph is bipartite and row (or column) biregular (see Figure 5.1). Finally, \(G\) is connected if as a directed graph is strongly connected.
5.2. Perron-regular graphs. We will identify all the Perron-regular (weighted) graphs.

**Proposition 5.1.** Let $G = (V, E)$ be a strongly connected directed graph and let $\omega : E \to (0, \infty)$ be a weight function. If $(G, \omega)$ is weight row (resp., column) regular, then it is row (resp., column) Perron-regular.

**Proof.** Since $(d, J_{|V|}) \ (\text{resp., } (d, J_{|V|}^T))$ is a right (resp., left) Perron eigenpair, the result follows from Theorem 4.8 for a column (resp., row) vector with all its entries equal to a given constant is always locally row (resp., column) constant (with respect to any square $R^+$-matrix with the appropriate size).

**Lemma 5.2.** Let $G = (V, E)$ be a directed graph which is connected by reversible paths and let $\omega : E \to (0, \infty)$ be a weight function. If $(G, \omega)$ is row (resp., column) Perron-regular, then the entries of a Perron vector of $A(G, \omega)$ take at most two distinct possible values. If in addition there exists a cycle of odd length which is a reversible path, then $(G, \omega)$ is weight row (resp., column) regular.

**Proof.** Again this is a direct consequence of Theorem 4.8 (see Figure 5.2).

**Corollary 5.3.** Suppose that $G$ is a graph which is not bipartite. If $G$ is (row or column) Perron-regular, then it is regular.

**Proof.** A graph is bipartite if and only if it possesses no odd cycles (see e.g. [4]), and then Lemma 5.2 implies the result since connected graphs are connected by reversible paths.

**Theorem 5.4.** A connected graph is row (resp., column) Perron-regular if and only if it is regular or bipartite biregular.

**Proof.** Connected regular graphs are both row and column Perron-regular by Proposition 5.1. Theorem 4.8 implies that connected bipartite biregular graphs are both row and column Perron-regular.

Conversely, suppose that a connected row (resp., column) Perron-regular graph $G = (V, E)$ is not regular. By Corollary 5.3, $G$ is bipartite. Let $V = V_1 \cup V_2$ be the...
A row Perron-regular weighted tree. The vertices are partitioned according to height parity (once a root is chosen, say a black vertex). It is row Perron-regular because $\delta^r_\omega(u) = 16$ and $\delta^r_\omega(v) = 4$ for every pair of vertices $u$ and $v$ of even and odd heights, respectively. According to the proof of Theorem 5.5, the corresponding Perron value is 8.
center, that makes it a rooted tree of height one.

**Proposition 5.6.** A tree is row (resp., column) Perron-regular if and only if it is a single vertex or a star. Moreover, if $A$ is the adjacency matrix of a star with $n + 1$ vertices, then

$$\lambda_A = \sqrt{n} \quad \text{and} \quad P_A = \left( \sqrt{n} \begin{bmatrix} 1^T_n \end{bmatrix} \right) \quad \text{(resp.,} \quad q_A = \left( \sqrt{n} \begin{bmatrix} 1^T_n \end{bmatrix} \right) \right). \quad (5.1)$$

**Proof.** Single vertices and stars are the only trees which are either regular or bipartite biregular. Therefore, the first claim follows from Theorem 5.4. (5.1) follows from the proof of Theorem 5.5.

### 5.4. Perron-regular degree.

Any strongly connected directed graph $G = (V, E)$ admits a weight function $\omega: E \rightarrow (0, \infty)$ such that $(G, \omega)$ is row (resp., column) Perron-regular, e.g. any weight function $\omega$ such that $(G, \omega)$ is weight row (resp., column) regular for in this case $J^T_{|V|} \quad \text{(resp.,} \quad J_{|V|}^T)$ is a right (resp., left) Perron vector. But there may exist less trivial weight functions giving rise to Perron-regular directed graphs, probably with Perron vectors having some entries distinct. The weighted row (resp., column) Perron-regular degree of $G$ is

$$\rho^r(G) = \max \left\{ |\{p_i^{(A(G, \omega))} : i \in V\}| : \omega: E \rightarrow (0, \infty) \quad \text{and} \quad A(G, \omega) \quad \text{is row Perron-regular} \right\}.$$

(resp., $\rho^c(G) = \max \left\{ |\{q_i^{(A(G, \omega))} : i \in V\}| : \omega: E \rightarrow (0, \infty) \quad \text{and} \quad A(G, \omega) \quad \text{is column Perron-regular} \right\}.$

Also, if $G$ is row (resp., column) Perron-regular, let the (unweighted) row (resp., column) Perron-regular degree of $G$ be

$$\rho^r_0(G) = |\{p_i^{(A^r(G))} : i \in V\}| \quad \text{(resp.,} \quad \rho^c_0(G) = |\{q_i^{(A^c(G))} : i \in V\}|)\).$$

If $G$ is a graph, then $\rho^r(G) = \rho^r_0(G)$ and $\rho^c(G) = \rho^c_0(G)$ and then we simply let $\rho(G) = \rho^r(G)$ and $\rho_0(G) = \rho^r_0(G)$.

### 5.5. Colonies.

Perron-regular degrees are bounded above by what we call the “colonial order”, i.e., by the number of “colonies”. A “colony” is a set of vertices that correspond to entries in a locally constant vector that are forced to be equal. To be precise, let $G = (V, E)$ be a strongly connected directed graph. For each $u \in V$ let

$$K^r_1(u) = N^r_1(u) \quad \text{(resp.,} \quad K^c_0(u) = N^c_0(u).$$
and define $K_G^{r,k}(v)$ (resp., $K_G^{c,k}(v)$) inductively for every $k \geq 1$ by the rule

$$K_G^{r,k}(u) = K_G^{r,k-1}(u) \cup \bigcup_{v \in V} \left\{ N_G^r(v) : K_G^{r,k-1}(u) \cap N_G^r(v) \neq \emptyset \right\}$$

(resp., $K_G^{c,k}(u) = K_G^{c,k-1}(u) \cup \bigcup_{v \in V} \left\{ N_G^c(v) : K_G^{c,k-1}(u) \cap N_G^c(v) \neq \emptyset \right\}$).

Then $K_G^{r,k}(u)$ (resp., $K_G^{c,k}(u)$) eventually stabilizes as $k \to \infty$ (because $|V| < \infty$), i.e., there exists $k_0 \geq 0$ such that $K_G^{r,k}(u) = K_G^{r,k_0}(u)$ (resp., $K_G^{c,k}(u) = K_G^{c,k_0}(u)$) for every $k \geq k_0$ (and for every $u \in V$ too, e.g. $k_0 \geq n$). Define $K_G^r(u) = N_G^{r,k_0}(u)$ (resp., $K_G^c(u) = N_G^{c,k_0}(u)$) and call it the row (resp., column) colony of $u$. By definition, for every $u, v \in V$, either $K_G^r(u) = K_G^c(v)$ (resp., $K_G^c(u) = K_G^r(v)$) or $K_G^r(u) \cap K_G^c(v) = \emptyset$ (resp., $K_G^c(u) \cap K_G^r(v) = \emptyset$), that is, the colonies of two distinct vertices are either equal or disjoint. Let $V^r$ (resp., $V^c$) be the set of row (resp., column) colonies of all the vertices in $V$, i.e.

$$V^r = \{K_G^r(u)\}_{u \in V} = \{V_1^r, \ldots, V_h^r\} \quad \text{(resp., } V^c = \{K_G^c(u)\}_{u \in V} = \{V_1^c, \ldots, V_h^c\}).$$

The row (resp., column) colonies form a partition of the vertex set. The row (resp., column) colonial order of $G$ is the number of distinct row (resp., column) colonies $h_r = h_r(G)$ (resp., $h_c = h_c(G)$). For example, if $G$ is a graph, then $h_r$ and $h_c$ are both equal to two if $G$ is bipartite, otherwise they are both equal to one (Theorem 5.5).

**Proposition 5.7.** Let $(G = (V,E),\omega)$ be a weighted directed graph and $A = A(G,\omega) \in \mathbf{I}$. Then $A$ is row (resp., column) Perron-regular if and only if for every $i = 1, \ldots, h_r$ (resp., $i = 1, \ldots, h_c$),

$$p_i^{(A)} = p_v^{(A)} \quad \text{(resp., } q_i^{(A)} = q_v^{(A)}),$$

for every $u,v \in V_i^r$ (resp., $u,v \in V_i^c$).

**Proof.** This is a direct consequence of Theorem 4.3 and the definition of colonies.

For any strongly connected directed graph $G$ we have

$$\rho^r(G) \leq h_r(G) \quad \text{and} \quad \rho^c(G) \leq h_c(G).$$

First we observe that on graphs the bound is attained. More precisely:

**Corollary 5.8.** Let $G = (V,E)$ be a connected graph. Then

$$\rho(G) = \begin{cases} 2 & \text{if } G \text{ is bipartite}, \\ 1 & \text{otherwise}. \end{cases}$$

4Hence, a colony consists of sets of neighborhoods.
Stochastic Forms of Non-Negative Matrices and Perron-Regularity

537

Fig. 5.4. A row (non-regular) Perron-regular directed graph \( G \). The row neighborhood structure of the digraph implies that the form of the locally row constant vectors is \((a, b, c, d, d, d, c, f, f, f)^T\), i.e., the row colonial order is five. The row colonies can be found with the following procedure:

Write a “symbolic” matrix so that the columns are distinguished symbols located according to the pattern of \( G \) (the transpose of \( A^\#(G) \)). Inductively merge two columns, leaving the symbols intact if there is no intersection, otherwise, choose one of the symbols and replace all the occurrences of the other symbols in the intersection by the chosen symbol. At the end a row colony is a set of vertices sharing the same symbol, and hence, the number of distinct symbols is the row colonial order. The right Perron vector of \( A^\#(G) \) is \((\lambda^6, \lambda^3, \lambda, 1, 1, 1, 1, 1, 1, 1)^T\), where \( \lambda = \sqrt[6]{6} \) is the corresponding Perron value. Then \( \rho_0(G) = 4 < 6 = h_r(G) \).

In particular, if \( G \) is a single vertex or a star, then

\[
\rho_0(G) = \begin{cases} 
2 & \text{if } G \text{ has at least three vertices}, \\
1 & \text{otherwise}.
\end{cases}
\]

Proof. It follows from Theorem 5.5 and Proposition 5.6.

Hence, for any connected graph \( G \) we have \( \rho(G) = h_r(G) \). Also if \( G \) is regular or bipartite biregular, then \( \rho_0(G) = h_r(G) \) unless \( G \) is a single edge. An example of a row Perron-regular directed graph \( G \) for which \( \rho_0(G) < h_r(G) \) is illustrated in Figure 5.4. Still the weighted Perron-regular degree always attains the upper bound for any strongly connected directed graph.

**Theorem 5.9.** Let \( G = (V, E) \) be a strongly connected directed graph. Then

\[
\rho^r(G) = h_r(G) \quad (\text{resp., } \rho^c(G) = h_c(G)).
\]

More precisely, for any row (resp., column) Perron-regular matrix \( A \), there exists a row (resp., column) Perron-regular matrix \( B \) such that \( P^r(A) = P^r(B) \) (resp., \( P^c(A) = P^c(B) \)) and the number of distinct entries in \( p_B \) (resp., \( q_B \)) is \( h_r(G(A^\#)) \) (resp., \( h_c(G(A^\#)) \)).

Proof. Let \( \omega : E \to X \) be a weight function such that \( (G, \omega) \) is row Perron-regular. Let \( A = A(G, \omega) \). Then \( p_A \) is locally row constant. For any other locally
row constant vector $v$, let $D \in \mathbb{D}$ be defined by $\text{diag}(D) = v$. By Corollary 5.11, the matrix $B = D^{-1}AD$ is row Perron-regular and yields the same Perron row stochastic form as $A$. Since $p_B = \frac{p_A}{v}$, we can find $v$ so that the claim holds.

The rest of the proof is analogous. \(\square\)

**5.6. Colonial directed graph.** By definition, there are surjective functions $\sigma^r, \tau^r: V \to \{1, \ldots, h_r\}$ (resp., $\sigma^c, \tau^c: V \to \{1, \ldots, h_c\}$) such that $u \in V_{\sigma^r(u)}$ and $N^r_G(u) \subset V_{\tau^r(u)}$ (resp., $u \in V_{\sigma^c(u)}$ and $N^c_G(u) \subset V_{\tau^c(u)}$) for every $u \in V$. Let

$$E^r = \{(V_{\sigma^r(v)}, V_{\tau^r(v)})\}_{v \in V} \quad \text{and} \quad E^c = \{(V_{\sigma^c(v)}, V_{\tau^c(v)})\}_{v \in V}.$$  

$G^r = (V^r, E^r)$ (resp., $G^c = (V^c, E^c)$) is the row (resp., column) colonial directed graph of $G$. It is strongly connected since $G$ is assumed to be strongly connected. Finally, given a weight function $\omega: E \to (0, \infty)$, let the weighted row (resp., column) degree structure be the labelling $L^r_\omega: E^r \to \text{Pow}^*(\{0, \infty\})$ (resp., $L^c_\omega: E^c \to \text{Pow}^*(\{0, \infty\})$) defined for every $e \in E^r$ (resp., $e \in E^c$) by

$$L^r_\omega(e) = \{\delta^r_\omega(v) : v \in V \text{ is such that } \sigma^r(v), \tau^r(v) = e\}.$$  

The (unweighted) row (resp., column) degree structure is the labelling $L^r_0 = L^c_0$ (resp., $L^r_0 = L^c_0$) for the weight function $\omega(e) = 1$ for every $e \in E$. An example is depicted in Figure 5.5.

**Proposition 5.10.** Let $G = (V, E)$ be a directed graph and $\omega: E \to (0, \infty)$ a weight function. If $|L^r_\omega(e)| > 1$ (resp., $|L^c_\omega(e)| > 1$) for some $e \in E^r$ (resp., $e \in E^c$), then $(G, \omega)$ is not row (resp., column) Perron-regular.

---

5Pow*(Y) denotes the set of non-empty finite subsets of the set Y.
Proof. It follows from Proposition 6.7.

Acknowledgments. We thank Stephen Kirkland for pointing out to us the Sinkhorn-Knopp construction. We are in debt with the referees for reading several preliminary versions of the paper; we thank their patience and all their recommendations and suggestions to improve the content and presentation of this work.
